JOURNAL OF RESEARCH of the National Bureau of Standards-A. Physics and Chemistry Vol. 67A, No. 2, March-April 1963

Third Spectrum of Palladium (Pd III)

A. G. Shenstone*

(November 2, 1962)

The Pd III spectrum has been observed from 688 to 2991 A, and the earlier analysis has been revised and extended. The number of Pd III lines here reported is 1,110, of which 917 are classified as combinations of 57 even energy levels with 111 of odd parity. The interpretation has been aided by theoretical predictions of the approximate positions of expected energy levels. Spectral terms from the $4d^{5}$, $4d^{7}ns^{4}$, and $4d^{6}5s^{1}5p^{1}$ configurations are designated. Eight limit terms are in the $4d^{7}$ ns^{1} configurations. The earlier ionization potential, 33.0 electron volts derived from the $(ns^{1})^{3.5}$ F series (n=5,6) by means of a Ritz formula, remains unchanged.

1. Introduction

Although a table of energy levels of the third spectrum of palladium was published in Atomic Energy Levels Vol. III[1]¹ in 1958, no description of the spectrum itself has appeared in print. Since the original analysis was done, I have made new measurements of the spectrum lines and have corrected and added to the analysis. While I was engaged in that work, the thesis of Dr. Yehudi Shadmi appeared in June 1961, with the title "A Systematic Treatment of the Low Configurations in the Spectra of the Transition Elements." His research extended the theoretical work started by Professor Racah [2] so that he was able to make a calculation of the even levels of the third spectra of the iron period and the first, second, and third spectra of the second long period. Palladium III was an important spectrum in that last group, being the last spectrum in the period of any considerable complication. Shadmi, who was in Princeton at the Institute for Advanced Study in 1961-62, also was good enough to ask one of his colleagues, Zvi Shimoni, in Jerusalem to calculate for me the positions of the odd levels of Pd III. As a result I have been able to correct the analysis in a number of points. They are discussed below.

2. Observations

The method of excitation of the spectrum was the same as that used for Ni III [3] with a number of refinements. The spark was operated in helium by using a transformer-condenser circuit with an auxiliary spark gap. The gap was a mercury gap, formerly part of an old induction furnace, and its present use gave considerably sharper spectra than the air gap used in recent years. Figure 1 shows the design of this useful and quiet gap. The accuracy of the level scheme was considerably improved

*Present address: Princeton University. ¹ Figures in brackets indicate the literature references at the end of this paper.

by new measurements of all the longer wavelength lines by means of our 21 ft 30,000 line per inch grating in a Paschen mounting. The lines of the third spectrum were first spotted by observing their polarity in spectra taken with a stigmatic mounting at smaller dispersion. This was necessary, of course, because of the great astigmatism of the Paschen instrument. The accurate measures were extended to the λ 1944 line of Cu II and were based on the copper lines as standards [4]. This wavelength range overlaps the strong oxygen absorption bands with the consequence that some strong Pd III lines are missing on the high dispersion photographs, and others are much weakened. This probably means that all the measurements below about 2000 A may be inaccurate due to absorption on one side or the other of the lines. In the part of the spectrum measured with the vacuum instrument only, the accuracy is somewhat better than in previous papers from this laboratory because of recent improvements in standards [5]. In table 1 from 1946 to 2197 A two sets of intensity estimates are listed: LG denotes the large grating and VG denotes the vacuum grating.

3. Analysis

The electronic structures which are responsible for Pd III are analogous, of course, to those of Ni III, but the change in the n's of the electrons produces very large differences in the level structure. The total spreads of energy in $4d^8$ and $4d^7$ 5s are only about 0.78 of those in $3d^8$ and $3d^7$ 4s but the spread of most of the individual terms is larger by a factor of over two. In consequence, there is a much greater mixing of terms and a great decrease in the individuality of the levels so that it becomes chiefly a matter of taste or convenience to use Russell-Saunders notation for many of the even levels and for a majority of the odd levels. The names chosen are mainly based on relative intensities of combinations, but some are based on analogy with other spectra. This leads to a considerable number of differences between my choice and those of

FIGURE 1. Mercury spark gap.

Shadmi and Shimoni although the numerical agreements between theory and observation are extraordinarily good.

4. Configurations $4d^8$ and $4d^7$ 5s

Shadmi's allocations differ from mine in one case only, the interchange of $a {}^{1}D_{2}$ and $a {}^{3}P_{2}$. The evidence for this change from intensities is ambiguous and I have preferred to retain my original choice.

There are, however, cases in which the theory does not predict significant mixing of identities, but where the experimental evidence does. The most important example is the mixing of $b {}^{3}F_{3}$ and $a {}^{5}P_{3}$ which are only 453 cm⁻¹ apart. That they share their combining properties to a very considerable extent is shown by the following selected pairs of intensities. With $z {}^{5}S_{2}^{\circ}$ the intensities are 200 and 300; with $z {}^{3}F_{2}^{\circ}$ 200 and 200; with $z {}^{3}G_{4}^{\circ}$ 500 and 250; with $z {}^{3}D_{3}^{\circ}$ 200 and 200; with $z {}^{5}P_{3}^{\circ}$ 150 and 200.

Two corrections amongst the even levels should be noted. $c {}^{3}P_{0}$ was incorrectly copied in my original manuscript and is now corrected. I have found, also, a new level $b {}^{3}D_{1}$ which fits both theory and observation better than the one which was previously reported and is now deleted. The only missing level of $4d^{7} 5s$ is $(b {}^{2}D)^{1}D_{2}$. A thorough search has been made for it with no result in spite of the guidance of Shadmi's prediction.

As usual, the ${}^{1}S_{0}$ of the d^{8} structure is missing. Its predicted position is so high that most of its combinations would lie in regions of the spectrum where very few lines have been observed. However, the theoretically predicted positions of $a {}^{1}S_{0}$ and $(b {}^{2}D)^{1}P_{1}^{\circ}$ differ by 118140 and there is a strong isolated and unidentified line at 117804 cm⁻¹. Since the sole parent of $d^{8} {}^{1}S_{0}$ in d^{7} is $b {}^{2}D$ this combination should be the strongest of all those possible. The only other lines which fall near predicted positions are the questionable ones at 82861 and 82800 cm⁻¹. If one of these is taken as $c {}^{3}P_{1} - (b {}^{2}D)^{1}P_{1}^{\circ}$ then $a {}^{1}S_{0}$ falls at 41112 or 41051 both of which are close to the predicted position 41196.

5. Configuration $4d^7 5p$

Although Shimoni's calculated odd levels agree numerically very well indeed with the empirical levels, there are many differences of interpretation. He gave in his communication to me the percentage composition of all the levels; and if one were to name each level to agree with its major component, there would be at least 15 more differences in interpretation than the 14 chosen by Shimoni.

Oddly enough, in the case of the important quintets built on the 4F of Pd IV Shimoni has chosen identifications which agree with mine, even though the percentage composition could in some levels lead to changes, and even though, also, this is the only set of levels for which I have used names based on an analogy in disagreement with the evidence of the intensities. In the isoelectronic sequences which begin with Fe I and Ru I, the identification of these levels in the arc spectra is the same whether based on intensities or *g*-values. It is quite otherwise in Co II [6] where the pattern of levels differs markedly from Fe I and where the evidence of the *q*-values is in considerable disagreement with the intensities. Since in Ni III, Rh II [1] and Pd III the pattern is more like Co II than Fe I, I have chosen the levels of Pd III by analogy with Co II and therefore in disagreement with the intensities. Figure 2 shows the two choices. In the triplet triad built on ⁴F of Pd IV, Shimoni has again chosen in agreement with me al-

FIGURE 2. 4d⁷ 5p [§]D°, F°, G°, as identified by analogy with Co II (on left) and by intensities (on right).

though the percentage composition of $z {}^{3}\mathbf{P}_{3}^{\circ}$ and $z {}^{3}\mathbf{D}_{3}^{\circ}$ is slightly in favor of an interchange. The intensities are somewhat ambiguous.

In the region of energies from 119000 to 129000 there are 45 odd levels, of which ten are named differently by Shimoni and myself. Figure 3 is a plot to show the two arrangements. The intensities are in favor of my identifications but there are certainly fundamental questions to be answered. For instance, the composition given for my $z {}^5P_3^{\circ}$ is 49 percent (⁴P)⁵D°, 17 percent (⁴P)³D°, 14 percent (⁴F)⁵D°, so that ⁵P° should be a very minor constituent in disagreement with the intensity observations. My $z {}^5P_2^{\circ}$ also has no major ${}^5P^{\circ}$ character in its makeup. These few examples indicate a very wide divergence in this respect between experiment and theory and a detailed examination would appear to be of importance. The levels at 119187 and 125477 which Shimoni calls respectively $({}^{2}P){}^{3}P_{1}^{\circ}$ and $({}^{4}P){}^{3}S_{1}^{\circ}$ could be interchanged and the lower one labeled $({}^{2}P){}^{3}S_{1}^{\circ}$ from intensities. The choice I made for 119187 ${}^{5}P_{1}^{\circ}$ however fits the intensities best.

In this part of the analysis, Shimoni's predictions of the positions of (2P)3P0 and (4P)3P0 made it possible for me to find these two levels, which are always elusive because of the paucity of combinations of levels of J=0. Amongst the higher terms there are a few more differences of naming, but more important is the fact that Shimoni's predictions led me to discover that my $w^{3}F_{2}^{\circ}$ is in reality $w^{3}G_{3}^{\circ}$; that my $x \, {}^{1}\mathrm{F}_{3}^{\circ}$ is $w \, {}^{3}\mathrm{F}_{2}^{\circ}$ and that my old $w \, {}^{3}\mathrm{G}_{3}^{\circ}$ is spurious. This cleared up the difficulty, that I had one too many levels with J=3. The only odd set of terms that is incomplete is the one based on the higher of the ²D terms of $4d^7$. $w^{3}P^{\circ}$ seems excellent but the fragments of ${}^{3}F^{\circ}$ and ${}^{3}D^{\circ}$ are all quite uncertain. They were chosen to fit the Shimoni analysis but the fact that levels such as ³F^o₄, which should give stronger lines, are missing makes them all doubtful. The level given in A. E. L. as $w \, {}^{3}\mathrm{D}_{3}^{\circ}$ is certainly spurious.

It is of considerable importance to find an accurate ionization potential by means of series and I, therefore, made a great effort to identify the levels of $4d^7$ (⁴F)6s and $4d^7$ (⁴F)5d which should lie at about 170,000 to 175,000, making combinations with the 5p levels in the range 1450 to 1700 A. Long exposures were made in this region and every possible

FIGURE 3. Some levels of 4d⁷ 5p as identified in this paper (on left) and as identified by Shimoni (on right).

line measured. The results were very disappointing, only 12 levels being retained as probably real. This is all the more surprising in that many complete terms were found in the corresponding structures of Co III. Of the levels here listed 1_5 is probably $6s \, {}^5F_5$ as given in A. E. L.; 2_4 is perhaps $6s \, {}^5F_4$ and 11_4 is about correct for $6s \, {}^3F_4$. The remainder cannot be identified except that it is certain that all but 11 and 12 are quintets. I cannot, therefore, give any evidence that will improve our knowledge of the ionization potential.

6. Configurations $4d^6 5s^2$ and $4d^6 5s 5p$

There remains the problem of the terms $4d^6 5s^2$ ⁵D and the various odd triads from $4d^{6}(^{5}D)5s 5p$. The position of the even ⁵D can be estimated from a consideration of various other spectra [7] as being between 128000 and 133000. Recently Shadmi has calculated the position for me as $131,500\pm1,000$ cm⁻¹. The structure $4d^6 5s 5p$ yields two sets of quintets based respectively on ⁶D and ⁴D of $4d^6 5s$. By analogy with Ru I, where both sets are identified, one can estimate that they should be separated by about 10,000 cm⁻¹. Also the lower triad gives lines in combination with the even ⁵D of nearly the same wave number as $4d^7 5s - 4d^7 5p$ which lie at about 54,000 $\rm cm^{-1}$. This would place the lower $4d^6 5s 5p$ quintet triad around $185,500 \pm 1,000$ and no levels at all have been found in that region. The higher quintets should lie about 10,000 higher and they may be represented by the levels 1 to 7° . This is an unsatisfactory conclusion because in both Fe 1 and Ru 1 the lower triad gives considerably stronger lines than the upper one.

The line list includes all the lines that can be assigned to Pd III with some certainty. Only in the region from 1500 to 1650 A where I took excessively long exposures have I eliminated a a considerable number of the measured lines which appear to be more probably due to Pd IV. Especially in this region some new source which develops the Pd III spectrum more completely and eliminates most of the lines of Pd IV is necessary if the higher structures are to be identified with any certainty.

There are a few unidentified lines in the region 680 to 800 A which are probably due to the structure $4d^6$ 5s 5p. In the region 1450 to 1700 A the many unidentified lines are undoubtedly due to structures $4d^7$ 6s and $4d^7$ 5d as discussed above or to Pd IV. In the part longer than 1950 A there are five unidentified lines of considerable strength. The only structures to which they can be attributed are $4d^7(b \ ^2D)5s$ and 5p, but no logical way of fitting them into the term scheme has been found.

The accuracy with which Shadmi's and Shimoni's predictions fit the numerical data makes it obvious that when a theoretical analysis of that kind is available, the experimentalist would be unwise to ignore it. Very definite empirical evidence would be necessary to justify any large difference between theory and experiment.

This research has been in part supported by the Higgins Fund of Princeton University. Mrs. Charlotte Moore Sitterly and the National Bureau of Standards have assisted in the preparation of the manuscript. I am much indebted to Mr. Zvi Shimoni for his kind permission to use his unpublished results in any way I wished.
