Abstract – The use of Enterprise Architectures is becoming increasingly widespread in the private sector. Borrowing insights from enterprise reference architectures developed during the last decade, IT vendors and companies belonging to specific industries are establishing reference data and process models advancing the standardization of their businesses and creating a more integrated environment for their activities. Although public administrations share the same problem of non-standardization, which is being magnified rapidly in a changing and demanding environment, little has been done so far in the direction of integration. This article builds a basis, shows initial directions and attempts to stimulate interest in a PA enterprise framework. Following a top-down approach and employing concepts from the fields of public administration, enterprise integration and generic process and data modeling the outline of the *ArchPad* enterprise architecture for Public Administration is presented.

I. INTRODUCTION

During the past few years significant changes are taking place in public administrations (PAs) all over the world. Citizens in all countries are calling for better services at lower cost, responsiveness in an unstable and ever changing political, economic, societal, technological (PEST) environment and administrations closer to their every-day life, acting primarily proactively rather than reactively.

Public Administrations in their quest to satisfy the aforementioned recent societal needs have borrowed management methodologies and practices that have been successfully tested in the Private Sector during the last two decades: Total Quality Management, Business Process Re-engineering, Learning Organization, Activity-Based Costing etc. For PAs following these trends and applying them, Information Technology has become a significant leverage factor.

In this context, a series of initiatives promoting and gradually establishing the notion of “e-governance” have taken place in the European Union either as independent activities or as parts of projects enhancing quality and efficiency in PAs. In the latter category, projects such as the British “Modernizing Government” [1], the Finnish “Quality Strategy of Public Services” [2] and the Greek “Kleisthenis Program for Modernizing Public Administration” [3] could be mentioned.

A. Defining the Problem

The use of leading-edge information technology to support these major efforts of reorganization, modernization and reinvention of government is not a simple task. The logic of

solely “automating” existing processes, while leaving the organizational structures, the human roles of PAs unchanged has proven to be unsuccessful.

Further the existence of isolated, overlapping in function and content, highly fragmented and unrelated computerized applications within the same PA organization has resulted in a major interoperability problem and has led to “isolated islands of technology” while Information Systems were viewed as being internal to the PA organization [4]. Until recently the ongoing need for inter-organizational exchange of information has become indispensable in the e-governance framework.

A serious need has emerged to analyze and redesign the tasks performed by each agency and ministry, exploring the ways in which various departments fit together, specifying their information processing needs and describing the human roles in each agent.

The need for integration of all systems calls for the formulation of a Reference Architecture for PAs. Of critical importance in this task of PA systems integration is the study of the intersection of their three basic systems [5] (Fig.1):

- Organizational Structures and Business Processes
- Information Systems
- Human Roles

The proposed Information Architecture for PA, *ArchPad*, is a framework for integrating processes, information systems and human roles. The core of *ArchPad* is a set of generic enterprise models for PAs at all levels of administrative hierarchy. *ArchPad* is oriented as much to the administrative experts as to the information systems departments. The goal of *ArchPad* is to contribute to the task of enhancing value, quality and cost efficiency in PAs.

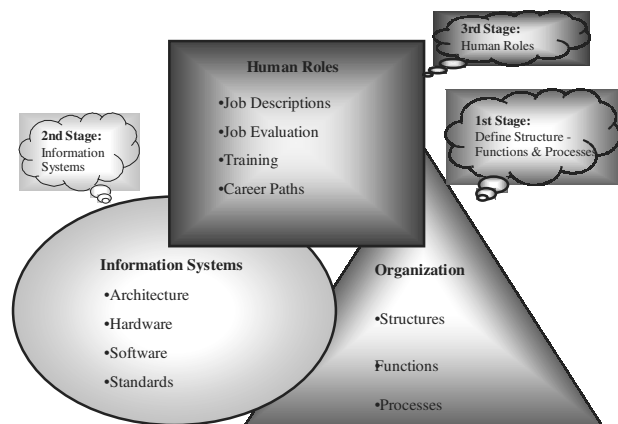

Fig. 1. The three systems of PA and their relation

Being an architecture, *ArchPad* represents a broad perspective and addresses requirements rather than a specific solution [6]. It aims at providing a basis for reshaping the business processes, the ability to reorganize the technology base, improve data integrity and delivery and allowing for consistent application development and more effective application integration. [7]

B. Motivation

During the nineties, a number of initiatives in the private sector, such as the Retail Application Architecture (RAA) [6][7], the Supply Chain Operations Reference-model (SCOR) [8] and the ARTS Retail Store Integrated Business View Data Model [9], among others, aimed at solving entrepreneurial problems similar to those presented in Section 1A. Problems regarding the data and information that the new, distributed enterprises were utilizing, the processes they executed and their inter-relations.

Specifically, RAA provides is a framework for retail application and information systems planning [6]. SCOR is a process reference model that provides a language for communicating among supply-chain partners [8], while on the other hand the ARTS Data Modeling initiative defined an industry standard data model which provides for software integration and interoperability [9].

Generic modeling is the common theme in these approaches where models (data, processes, etc) which apply to any enterprise or any industrial sector are developed. The generic models developed as part of the ARTS and SCOR efforts involve data and processes respectively, while the RAA Framework includes both types of models. Generic modeling for other systems of the enterprise (e.g. human roles) has received little attention.

Specific industries such as retail realized the pressure to communicate using a standard language, with reusable elements. Redesign projects and IS development also gain from such a language. Minimally the language provides a means of communicating among units; maximally the language provides a means of representing knowledge for use in the enterprise [10].

Similar issues led IT vendors such as SAP and IDS to formulate ready-to-configure solutions covering specific industries and creating generic industry process and data models .

During the same period, significant progress has been made in the Public Sector throughout Europe, both in reorganizing and in introducing computer systems and applications. The “Kleisthenis Program (1994-99)” funded both by the European Union and the Greek Government with a total amount of approx. 150 MECUs, constituted the main program for public sector modernization in Greece. At the heart of the Program was the belief that better PA and modernization of the State is possible by investing in IT, human capital and reorganization [11].

Although in the right direction, the intersection of the three systems (structures, humans, IT) (see Fig.1) has not received the required attention during the Program. As a result at its conclusion, a widespread feeling of “island” systems exists. In fact, three such cases exist:

- IT islands,
- training islands not always in correspondence with the specific needs and
- structural islands that emerged from some interesting yet fragmented re-engineering projects that certainly didn't alter the model of Greek PA.

The drive for integration, through the definition of Generic Process, Data and Human Models, remains basically the same regardless of whether in the private or the public sector. Although many initiatives facilitate the integration of data and processes in many industries in the private sector, PAs are relatively far behind in this path. They will soon face serious problems, as they rapidly change the way they operate, become more open and citizen-oriented. The specification of a Reference Architecture for PAs is needed and timely.

In the first section of this paper we review the state-of-the-art in Generic Information Systems Architectures, we then attempt to pinpoint and list the Major Processes of PA and give an example of our approach using a mapping methodology. Finally we suggest some paths for future work.

II. STATE-OF-THE-ART IN GENERIC INFORMATION SYSTEM ARCHITECTURE

The basic motivation and the significance of building generic process and data models were presented in the previous section. In this section a review of the state-of-the-art is presented on the specification of generic information system architecture. This review is structured around Table I which groups various initiatives in this area that have taken place during the last decade. The grouping is built along two axes. The horizontal axis classifies the approaches with respect to WHAT they have tried to model. There are three options for this: modeling data, processes or both.

The vertical axis provides the SCOPE of the models. Three options exist here, as well. At the first level there are frameworks, meta-frameworks (frameworks about how to build frameworks) and methodologies that have been proposed in order to create generic models. This first level serves as a repository or a library that can be consulted before building any kind of generic (process or data) model. At the second level exist generic process & data models. While at the third level examples of specific instantiations of generic data and process models for specific industrial sectors are provided.

	DATA & PROCESS	PROCESS	DATA

The aforementioned taxonomy generates nine cells. The list of approaches that occupy each cell is far from exhaustive. The criterion of choice was the insights these approaches provided to our proposal. As a result, this led to a larger in comparison number of frameworks for building integrated generic models and generic process models since this was the main focus.

The cell in the upper left-hand corner is the most generic and closest to the notion of an “architecture”. First in the cells appears the IFIP-IFAC Task Force General Enterprise Reference Architecture Methodology (GERAM) [12]. IFIP and IFAC set up the Task Force on Architectures for Integrating Manufacturing Activities and Enterprises in 1990, with the aim of defining and evaluating Enterprise Reference Architectures. That is, GERAM constitutes a meta-framework for building Enterprise Reference Architecture. It’s latest version GERAM 1.6.2, was submitted to ISO TC184/SC5/WG1 for inclusion as an annex to ISO WD15704, “Requirements for enterprise-reference architectures and methodologies” [7]. GERAM defines a tool-kit of concepts for designing and maintaining enterprises over their entire life-cycle. GERAM is not yet-another-proposal for an enterprise reference architecture, but it aimed at organizing existing enterprise integration knowledge. The framework has the potential for application to all types of enterprises.

Also in this cell appears the Information Systems Architecture (ISA) introduced by Zachman [13] in 1987 and completed five years later [14]. Zachman specified the area of Information Systems architectures motivated primarily by the increasing size and complexity of the implementations of

information systems. The architecture that was defined included logical constructs to define and control system integration.

In 1991, through the AMICE project of the ESPRIT program, the CIM-based, CIM-Open Standards Architecture (CIMOSA) framework was developed [15]. CIMOSA can be considered as the first GERAM, although the term was coined later. In fact CIMOSA contributed its basis to the IFIP-IFAC GERAM. The 3-D cube framework of CIMOSA provided and continues to provide a lot of insights to modeling undertakings.

A year later a second GERAM was presented from Purdue University: the Purdue Enterprise Reference Architecture (PERA) [16] [17] also based on CIM.

The ARIS framework [18] [19] was also accompanied by a fully computerized toolset and has become a leading process modeling front-end. The CIMOSA approach is prominent in ARIS both in its life-cycle dimension and in the different enterprise “views” it supports.

The GRAI Integrated Methodology (GIM) [20] was among the first to model decision structures in CIM.

The Toronto Virtual Enterprise (TOVE) is a project of the University of Toronto. The project aimed at four goals [21]. TOVE proposed a set of integrated ontologies for representing enterprises spanning activities, states, time, organization, resources and products [12]. TOVE also implement the semantics in a set of axioms that will enable TOVE to automatically deduce the answer to many “common sense” questions about the enterprise.

The Enterprise project, budgeted at over 4 MECU by the British government, was the UK’s major initiative to

promote the use of knowledge-based systems in enterprise modeling. It aimed at supporting organizations in the Management of Change. During the project, the Enterprise Toolset was developed. The Toolset employs executable process models to help users perform their tasks [23].

The Convergent Engineering approach [24] is an implementation of object-oriented logic in enterprise modeling.

Ontoligua is part of the Knowledge Sharing Project at Stanford University [25]. As in TOVE, Ontologies is the main subject of study in the project. Ontologies provide a vocabulary for representing and communicating knowledge about some topic and a set of relationships that hold among the terms in that vocabulary [26].

In the process column of the first level of the taxonomy, one finds the Process Handbook (PH) from M.I.T. The PH was developed at MIT by the Center for Coordination Science. It is basically a process repository, based on a representation that exploits two sources: (1) specialization of processes based on inheritance of object-oriented programming, and (2) concepts about managing dependencies from coordination theory. [29-34]

The grammar of processes exists in the same cell. The metaphor of “grammar” is extensively used and it has been developed into a rigorous model applicable in empirical research [35]. For this approach the Process Handbook is a useful repository, serving as a large lexicon of process steps and constraints on the ways in which they can be combined [36].

The second level of the taxonomy contains Generic Process/Data Model approaches. In the Data & Process column, the SAP Reference Model is placed. This model is the basis of the R/3 logic. It joins both processes and data models in a generic representation of the enterprise [38].

The Federal Enterprise Architecture Framework was developed by the Chief Information Officers Council (CIO Council) in the USA. The Federal Enterprise Architecture serves as a governmental strategic information asset base that defines the business information necessary to operate the business, the technologies necessary to support the business operations, and transitional processes for implementing new technologies in response to the changing needs of the business[27]. The proposed framework is based on two methodological pillars : the Zachman Framework and Dr. Steven Spewak’s Enterprise Architecture Planning[28]. The Federal Enterprise Architecture Framework promotes shared development for common Federal processes, interoperability, and sharing of information among Federal Agencies and other Governmental entities. The latest version of the Framework was published in September 1999 and could be considered the most significant pilot initiative towards the creation of an architecture for PAs.

In the Process column, one finds the generic models of the Government Process Classification Scheme (PCS) from Inter-Agency Benchmarking & Best Practices Council [39]

the Inter-national Benchmarking Clearinghouse (IBCCF) [40], the Lean Enterprise Model [41] and the European Foundation for Quality Management Excellence Model [42] serving as basis for re-engineering, benchmarking and best practices efforts in different industries due to their generic character.

PCS is a taxonomy of common government processes to be used for collecting and sharing “best practices”. The four major processes of “Establish Direction”, “Acquire Resources”, “Provide Capabilities” and “Execute the [Agency’s] Mission” are further analyzed providing over 150 fourth level processes [39]. The specific taxonomy could serve as a useful repository of government executed processes. The framework is obviously process-oriented as the established classification is based on a horizontal view rather than a functional taxonomy and is thus applicable to the whole of the PA’s functions.

The IBCCF model consists of thirteen generic processes that describe the operation of any private sector organization. This first level of processes is further decomposed into a second and third level of increasing detail. A latest version of the EFQM Model, tuned for non-profit organizations, has been extensively applied to Public Sector benchmarking [44] during the British “Benchmarking Project”. Also, the Phios repository is the commercial version of the aforementioned Process Handbook from MIT [43] with an extensive library of processes.

The Data column of the second level contains references to the work of L. Silverstone, W.H.Inmon and K. Graziano [45] and David C.Hay [46] who proposed generic data models applicable to a wide range of different enterprises.

The Interchange of Data between Administrations Architecture is an effort in the data column, too. This was developed through the European IDA I Program [37]. The fundamental concept is that of a homogeneous Europe-wide facility, the EuroDomain, which allows the exchange of data between disparate or similar IT-systems of local Administrations, the Local Domains. The EuroDomain is foreseen to be established as a homogeneous set of actual, pan-European value-added network services. The emphasis is on the service provided by the EuroDomain. The delineation of responsibility between Local Domains and the EuroDomain is achieved through the vehicle of an access point, called the EuroGate, which is an identifiable module connecting a Local Domain to the EuroDomain. The EuroGate is a key architecture element providing both the flexibility and the managerial and technical independence between the Domains.

The Structured Systems Analysis And Design Method (SSADM) was an interesting early attempt in data modeling by the UK government. It was developed by CCTA (Central Computer and Telecommunications Agency) in the early 1980’s.

Finally at the third level of the taxonomy, exist some examples of the numerous implementations in specific

industrial sectors (partial scope models as defined by GERAM-CIMOSA).

In the Data & Process column the SAP Industry Solution Maps define the business processes of an industry and map these processes to the actual SAP products in order to enable the easy evaluation and implementation of an information technology business solution [47]. The ARIS Industries Reference Models illustrate industry specific processes, data and function structures. [48]

In the Process column, the need to build a common language in industries (e.g. health [49][50] and supply-chain[8]) has led to the identification of the few major processes that describe the whole action in a specific field. For example, the Alternative Carrier Reference Model (ACRM) for telecommunication companies developed by IDS in collaboration with Nokia telecommunications, provides alternative telecommunication carriers with reference structures that allow individual, fast, and cost-effective customization and optimization of business processes [51].

Finally, in the Data column, the ARTS Model and the sector projects financed by the IDA I project could be placed [53]

III. MAJOR PROCESSES IN PAs

A. Defining the Major Processes-Methodology

All generic modeling frameworks, placed in the first level of the taxonomy of Section 2, begin the modeling of an enterprise with a function (or process) definition procedure [12][15][18]. This provides the basis for further information system (or model) building. A similar start point can be employed in building a reference architecture for PA. The key questions at this point are:

- which are the major-generic processes performed by all PAs regardless of the tasks they execute and the services they produce?
- in what way can the processes of PA be represented?

In order to answer the first question, the three-layer management model describing any organization (also referred to as the staff/line model [53]) was employed, that is :

- the strategic layer
- the operations layer
- the support layer.

Their adaptation to a PA environment provides respectively the three generic functions that characterize PA:

- formulate Public Policy
- provide services
- support operations

The above are the first level generic processes that could describe any kind of activity that occurs in PA (see Fig.2).

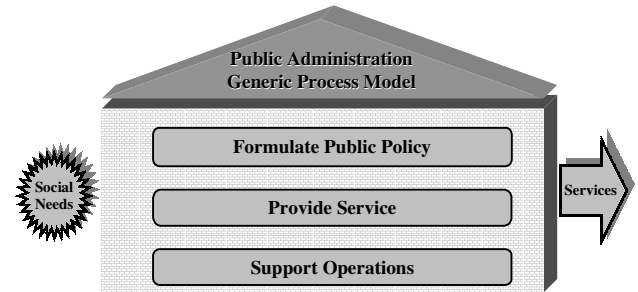

Fig.2. Major Processes in PA

There are important reciprocal interrelations among these three generic processes. More importantly, the link between the “Formulate Public Policy” process and the “Provide Services” is quite strong and demonstrates the former process more as a learning and evolutionary procedure rather than a simple predefined executable task [54].

These three generic processes are then compared to processes in the IBCCF framework as well as to models found in the PA literature. The IBCCF provides thirteen generic (first level) processes appropriate to describe any kind of service-oriented organization. Important changes on the IBCCF model were required in order to tune it in the PA needs. In particular, the “Formulate Public Policy” (FPP) process of the public domain differs fundamentally from its corresponding process, “Develop Vision & Strategy”, of IBCCF [40] as it is based on a public policy analysis model.

Subsequently, the MIT Process Handbook methodology is employed as a process mapping technique. The three notions of decomposition, specialization and bundles [29][34] were found to be particularly powerful in providing a useful and meaningful representation of PA processes.

The decomposition notion is used by all process representation techniques and it is based on the assumption that all processes can be broken down (or decomposed) into sub-parts (or sub-activities) [29].

Specialization is the second notion provided by the Process Handbook (PH). This concept was borrowed from object-oriented programming. The inheritance process allows instances of a specific process to both inherit characteristics from its parent (more generic) process and maintain specific characteristics or components as well. In generic process modeling, this is a particular useful concept which helps instantiate a prototype, defined by a generic process model, for the specific organization being modeled.

While a sub-activity represents a part of a process, a specialization represents a “way of” doing the process [29].

The third notion of the PH representation that is used is the “bundle”. A bundle is created with the grouping of related alternatives of specialization. In PH methodology there are usually more than one way to specialize a process. These alternative ways of performing specializations are called “bundles” in the PH framework.

B. The Proposed Model

B.1. Formulate Public Policy

The first generic process of “Formulate Public Policy” can be decomposed using the policy analysis model presented by B.W. Hogwood and L.A. Gunn [55]. As part of the *ArchPad* architecture, a PA specific model was built rather than adopting the IBCCF “Develop Vision & Strategy” process for reasons mentioned above.

At the second level of this process, the upper level process is decomposed into eight sub-processes (see Fig.3).

Fig. 3. Decomposition of the “Formulate Public Policy” major process

B.2. Provide Services

The second generic process, “Provide Services” can also be decomposed. In this task, IBCCF processes are utilized, but are significantly altered. The “Design Products and Services” and the “Produce and Deliver for Service-Oriented Organization” processes of IBCCF, after being adapted into the PA framework, result in the four second-level processes exhibited in Fig.4.

We proceed by analyzing the “Provide Service” process using specialization. There could be two different bundles of specialization: one based on the “Provide WHAT KIND of Service?” question and one on the “WHO Provides the Service?”. This first level of specialization is shown by the “WHO” and “WHAT” arrows, which emanate from the “Provide Service” generic process (see Fig.5).

Answering the first question provides a “bundle” of specialization based on the WHAT question. Using a common taxonomy of PA services in the relevant literature [49] the categories “Provide Regulations” and “Provide Public Common Goods & Services” [56] can be employed. Each of the “Provide Regulations” and “Provide Common Goods & Services” processes inherits the sub-processes of their common parent process “Provide Service” (Fig.4). This inheritance however does not prohibit altering,

Fig. 4. Decomposition of the “Provide Service” major process

adapting or even erasing a part of the parent process according to the specific needs of the newly specialized processes. As an example, the “Produce” sub-process will be passed to both specialized processes but with a different meaning: “Produce” becomes “Vote/Decide” in providing regulations and “Make/Buy” in providing public goods. Similarly the “Design Service” generic sub-process will become “Design Regulation” and “Design Common Goods” respectively. These two would fundamentally differ and their differences should emerge, when the next (third) level of decomposition is built.

The first level of the “WHAT” bundle is further specialized as Fig. 5 illustrates. Asking the question “WHO Provides the Regulations” could formulate an interesting bundle based on WHO. Three sources of regulations provision could be detected based on Montesque’s classical separation of powers in the State:

- “Provide Legislative Acts”,
- “Provide Judicial Decisions”,
- “Provide Administrative Acts”.

Of course at the lower levels of the representation, completely different processes would appear as different chains of processes describe the ways in which the parliament legislates, the courts judge and PA produces Acts. For example, all of these processes have a “Communicate & Deliver” sub-process, but it is likely that it will be executed differently.

In Fig.5 an additional second-level specialization is shown. The “Provide Public Common Goods & Services” first-level specialization can be further specialized with the “WHAT KIND of Public Common Goods & Services?” question. A second-level specialization is provided in two versions: “Provide distributive Goods & Services” and “Provide redistributive Goods & Services”. This categorization is common in the PA literature [56][57][58].

The “Provide distributive Goods & Services” process describes the production of services which, for various reasons, the free market fails to produce (at all or in efficient quantities) (e.g. parks, seaports, roads, defense). On the other hand, the “Provide redistributive Goods & Services” describes the intervention of the State in the Market in order to enhance social justice [58] (e.g. health systems, social security-insurance, public education). The above concepts correspond to Buchanan’s productive and protective state [59].

Going back to the generic (first) level, we could specialize the “Provide Services” process using the question “Who Provides the Service?”. Answering this WHO question could provide a second bundle of specialization to the first-level parent process. A service could be “Provided Centrally”, “Provided Regionally” or “Provided Locally”. The criterion for this specialization is not merely geographical but mainly administrative. The whole framework alters as one moves from central to local provision of services.

The sub-processes of these three types of service provision have been inherited from their parent process.

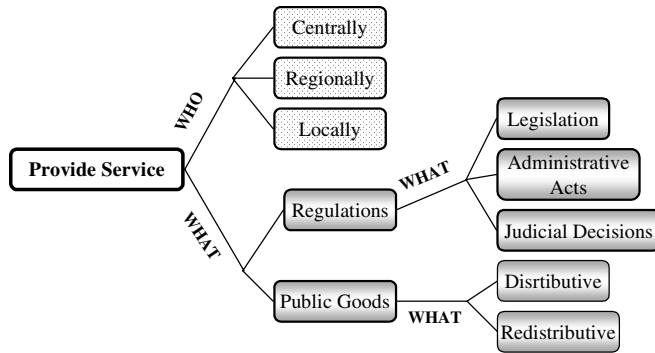

Fig.5. Specialization of the “Provide Service” major process

The “Communicate & Deliver” sub-process in “services centrally provided” is not the same as the “Communicate & Deliver” process in “services locally provided”. Their differences will certainly appear when the decomposition is carried further.

B.3. Support Operations

The third generic process, “Support Operations”, is specialized employing the IBCCF model. In Fig.6 three specializations are shown based on the question “WHAT KIND of Support Operations”.

The models that result when analyzing this third generic process do not differ significantly from those of the private sector (i.e. support operations whether in private or in public sector are about the same). Both the IBCCF and the Phios Process Repository (PPR), mentioned in Section 2, could serve as a ready-to-use process library solution; the later accommodating a rather impressive number of processes with helpful descriptions (aprox. 6000).

Fig.6. Specialization of the “Support Operations” major process

Obviously both decomposition and specialization tasks could be performed further with the support of PA theories and models. The ArchPad model appears more generic at the highest level and gradually becomes more PA-specific as

we proceed to lower levels, analyzing it using decomposition and specialization

V. IMPLICATIONS FOR FUTURE RESEARCH

This paper has presented the need for building an Information Architecture for Public Administration. It proposed a model based both on PA theory and on Information Systems literature. It aims at providing a stimulus for further research in a field that is little explored until now.

As part of future work we intend to continue developing ArchPad based on other theories of PA as well as a bottom-up approach which will include empirical research. The latter will provide the model with data, enforcing its validity and applicability to the whole PA framework. Analyzing numerous specific examples of process execution accompanied by their data models and the organizations in which they are executed, would create a useful PA-specific process/data/structure use-case library, which could be used in re-engineering, benchmarking and integrated Information Systems development.

If PA is to provide an enhanced level of service and participate in the developments of the “Information Society” then an architecture to base this evolution is needed and timely.
