#### Abstract

Attempts of synthesis of ionic $\left(\mathrm{NH}_{4}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)$ using metathetical approach resulted in a mixture of the target compound and a partly dehydrogenated molecular $\mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}$ product. The mixed specimen was characterized by NMR and vibrational spectroscopies, and the crystal structure of their cocrystal was solved from powder x-ray diffraction data, and supplemented by theoretical density functional theory calculations. Despite their impressive hydrogen content, and similarly to ammonia borane, both title compounds release hydrogen substantially polluted with borazine, and traces of ammonia and diborane.

## Introduction

Protic-hydridic compounds constitute one important family of solid-state hydrogen storage materials with the potential to be applied as onboard fuel systems required in the hydrogen economy. The presence of both positively and negatively charged hydrogen atoms results in the formation of a network of dihydrogen bonds governing the crystal structure and facilitating the process of thermal decomposition. ${ }^{1}$ These features were observed and thoroughly described for ammonia borane, ${ }^{2}$ metal amidoboranes, ${ }^{3}$ and further explored for $\mathrm{NH}_{4} \mathrm{BH}_{4} .{ }^{4}$

Ammonia borane (AB) is one of the best-researched materials in this group, being an air and water insensitive solid and containing ca. $19.6 \%$ of hydrogen by weight. ${ }^{5}$ Unfortunately, AB releases only $1 / 3$ of the stored hydrogen below $120^{\circ} \mathrm{C} .{ }^{6}$ Moreover, the hydrogen released is contaminated with ammonia, diborane, borazine, aminoborane and aminodiborane, which excludes its use as a direct $\mathrm{H}_{2}$ source for low-temperature fuel cells. ${ }^{7}$ Such high gravimetric H content, however, provides significant room for modifications even if the relatively heavy elements are introduced, the system still should be able to fulfil the gravimetric DOE requirements for H storage materials (Fig. 1). ${ }^{8}$

Among the derivatives of $A B$, amidoborane salts of a general formula $\mathrm{M}\left(\mathrm{NH}_{2} \mathrm{BH}_{3}\right)_{n}$ [abbreviated here as MAB or $\mathrm{M}(\mathrm{AB})_{n}$ ] constitute the largest group. ${ }^{9,10}$ Two dozens of mono- and bimetallic amidoborane salts have been reported. Some of them [i.e. KAB, ${ }^{11} \mathrm{RbAB},{ }^{12,13} \mathrm{CsAB},{ }^{12,13} \mathrm{Mg}(\mathrm{AB})_{2},{ }^{14} \mathrm{Ba}(\mathrm{AB})_{2},^{15}$ $\mathrm{Al}(\mathrm{AB})_{3}{ }^{16} \mathrm{LiAl}(\mathrm{AB})_{4}{ }^{17}, \mathrm{Li}_{2} \mathrm{Mg}(\mathrm{AB})_{4}{ }^{18}$, ] evolve pure $\mathrm{H}_{2}$ upon thermal decomposition at $c a .100^{\circ} \mathrm{C}$. Nonetheless, all these materials suffer from a lack of reversibility and relatively low hydrogen content available at moderate temperatures. 9,10
Recently, a novel group of ammonia borane derivatives containing five-membered chain anions of a general formula $\mathrm{M}\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)$ [abbreviated here as $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ ] have

[^0]been reported. ${ }^{19-23}$ Among them, one can list two allotropes of Verkade's base salt ${ }^{20,21}$, five alkali metal salts ${ }^{19,21,22,24,25}$ and four ionic liquids. ${ }^{23}$. Although three of them [i.e. $\mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2)^{21,22}$, $\left.\left(\mathrm{Bu}_{4} \mathrm{~N}\right)(\mathrm{B} 3 \mathrm{~N} 2),{ }^{23}\left(\mathrm{Et}_{4} \mathrm{~N}\right)(\mathrm{B} 3 \mathrm{~N} 2)^{23}\right]$ meet the target H wt\% content and release pure hydrogen below $150^{\circ} \mathrm{C}$, yet none of them fulfils all the DOE targets simultaneously. ${ }^{8}$

Fig. 1. Hydrogen content of monometallic amidoboranes (black), bimetallic amidoboranes (grey), $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2$ ) salts (magenta) as a function of reporting date. ## Results and discussion

### 2.1 Synthesis

Synthesis of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ was attempted employing Jaron's et al. metathetic approach mediated by the precursors containing weakly coordinating ions ${ }^{26-28}$. The reaction was conducted in dry THF similarly to the previous syntheses of all alkali metal $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts ${ }^{21}$ according to Equation 1:

$$
\begin{align*}
& (\mathrm{VBH})\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)+\left(\mathrm{NH}_{4}\right)\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right] \\
\rightarrow & \rightarrow  \tag{1}\\
& \left(\mathrm{NH}_{4}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)+(\mathrm{VBH})\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]
\end{align*}
$$

Unexpectedly, during the reaction, we observed the evolution of a small amount of gas which should not occur in a metathetic reaction. Since the expected main product contains ammonium cation and B3N2- anion (essentially, a derivative of a borohydride anion) we assumed that - similarly to what is observed for $\mathrm{NH}_{4} \mathrm{BH}_{4}{ }^{29}$ - hydrogen might be evolved upon reaction of these ions according to Equation 2:

$$
\begin{equation*}
\left(\mathrm{NH}_{4}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right) \rightarrow \mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}+\mathrm{H}_{2} \uparrow \tag{2}
\end{equation*}
$$

Confirmation that this surmise is correct is presented below.
Synthesis led to a mixture of well THF-soluble products, which were separated by precipitation of the side product (VBH) $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]$ in dry DCM. Both products were subjected to spectroscopic analyses (Fig. 2) and powder X-ray diffraction (Fig. 3) to demonstrate successful ion exchange according to Eq. 1. Indeed, FTIR spectra (Fig. 2) of the products show that the target product contains the NH and BH groups, while the side product contains the CH groups. Unfortunately, complete separation of the main product and side product was not achieved, as documented by very weak CH bands at $c a .3000 \mathrm{~cm}^{-1}$ from $\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}{ }^{-}$anions for the former, and very weak BH bands at $c a$. $2400 \mathrm{~cm}^{-1}$ from (B3N2)- anions for the latter product. X-ray

Fig. 3. Comparison of powder X-ray diffraction patterns of precursors and products of metathetic synthesis performed according to Eq. 1. $\operatorname{CoK}_{\alpha 1,2}, \lambda=1.78901$ Å.
diffraction points to the same conclusion, showing that two new distinct crystalline species formed during the reaction (Fig. 3). The diffraction patterns of the products are free from reflections coming from the substrates which suggests at least $95 \%$ purity of the former.

### 2.2 NMR spectra

A detailed ${ }^{11} \mathrm{~B}$ NMR investigation of the main product dissolved in THF-d ${ }_{8}$ was performed (Fig. 4). A typical spectrum of M(B3N2) salt consists of a triplet at ca. -8.5 ppm from [BH2] groups and a quartet at ca. $\mathbf{- 2 2 . 5} \mathrm{ppm}$ from [ BH 3 ] groups, having a relative intensity of 1:2). ${ }^{20,21}$ Here, the spectrum of the main product is more complicated and contains two triplets ( $\delta=-10.4 \mathrm{ppm}, \mathrm{J}=$ $101 \mathrm{~Hz} ; \delta=-12.3 \mathrm{ppm}, \mathrm{J}=102 \mathrm{~Hz}$ ) and a quartet ( $\delta=-22.2 \mathrm{ppm}$, $J=91 \mathrm{~Hz}$ ) in an intensity ratio that varies from batch to batch (in average ca. 4:3:5). These features altogether suggest that the main product formed according to (Eq. 1) partially undergoes a subsequent dehydrogenation reaction (Eq. 2). Variation in the observed intensity ratio of the signals may be caused by the partial decomposition of the main product thus changing the ratio between the components of the product. We note that a 1:3 mixture of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ and $\mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}$ (abbreviated as N3B3) would yield $4 \mathrm{BH}_{2}$ triplets units coordinated by two $\mathrm{NH}_{2}$ groups, $3 \mathrm{BH}_{2}$ triplets from units coordinated by $\mathrm{NH}_{2}$ and $\mathrm{NH}_{3}$, and $5 \mathrm{BH}_{3}$ quartets altogether. This result would suggest that ca. $3 / 4$ of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ decomposed to N3B3 while dissolved in THF.

To get more insights into the processes occurring during the synthesis, we conducted in situ ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR measurements in THF- $\mathrm{d}_{8}$ to monitor signals of the products and substrates (Fig. 5). The monitoring showed that all three signals from the product(s) (marked with \#) arise simultaneously, testifying to the simultaneous progress of reactions described by Eq. 1 and Eq.2. Apart from the signals assigned to the substrates and the main product, numerous additional signals which do not change during the reaction are present. These signals come from the moieties that do not play a direct role in the formation of the main product, e.g. $\left[B\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]^{-}$, in which the chemical neighbourhood of boron atom does not change during the

Fig. 4. Comparison of ${ }^{11} \mathrm{~B}$ NMR spectra of the main product of the synthesis according to Eq. 1 (magenta lines) with the spectra of a product of reaction according to Eq. 2 reported by Ewing et al. ${ }^{19}$ (black lines) both with (bottom spectrum). Boron spectra show with and without ${ }^{1} \mathrm{H}$ decoupling. * indicates $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]^{-}$anions.
synthesis. The monitored reaction (Fig. 4) was not completed (i.e. signals of the substrates were still intense) because of the local depletion of the substrates (no mixing was applied in an NMR test tube inside the spectrometer).

It is worth mentioning that ${ }^{11} \mathrm{~B}$ NMR spectrum of the main product(s) is very similar to the spectrum reported by Ewing et al. in 2013, having the same pattern of three signals: two triplets ( $\delta=-10.5 \mathrm{ppm}, \mathrm{J}=95 \mathrm{~Hz} ; \delta=-12.4 \mathrm{ppm}, \mathrm{J}=104 \mathrm{~Hz}$ ) and a quartet $(\delta=-22.3 \mathrm{ppm}, \mathrm{J}=95 \mathrm{~Hz})^{19}$ with 4.1:3.2:5.0 intensity ratio of the signals (according to our analysis of graphical data show in that study, Fig. 9a in Ref. [19]). The report of Ewing et al. focused on the synthesis of a neutral 6-membered chain molecule, B3N3, via a direct reaction between $\mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2)$ and ammonium chloride, according to the following equation: ${ }^{19}$

$$
\begin{equation*}
\mathrm{Na}\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)+\mathrm{NH}_{4} \mathrm{Cl} \rightarrow \tag{3}
\end{equation*}
$$

$\rightarrow \mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}+\mathrm{H}_{2} \uparrow+\mathrm{NaCl} \downarrow$
The reaction, performed in glyme solution, was accompanied by evolution of hydrogen gas, which is similar to our observations.

Ewing et al. assumed that the solid product obtained was B3N3 based only on an NMR study of this material. ${ }^{19}$ Three signals observed were assigned to three boron-containing groups present in the molecule (two $\mathrm{BH}_{2}$, one $\mathrm{BH}_{3}$ ). In the case of successful synthesis of B3N3, however, all signals observed

The bottom spectrum shows the mixture of substrates ( $\mathrm{t}=60 \mathrm{~s}$ ). The top spectrum shows to final mixture of products and substrates ( $\mathrm{t}=6060 \mathrm{~s}$ ). @ indicates signals from substrates. \# indicates signals of the main product. * indicates $\left[B\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]^{-}$anions.
should be equally intense (1:1:1) while their intensity ratio was clearly different (Fig. 4). Our analysis suggest that the reaction towards B3N3 is in fact a two-step process (Eqn. 1 and 2) and some $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ intermediate (i.e. our main target
compound) remains. The resulting assignment of NMR signals for both products is given in Table 1.

To further support our claim, we performed further characterisation of the reaction product.

### 2.3 FTIR and Raman analysis

Two preeminent sets of bands in the vibrational (IR absorption and Raman scattering) spectra of the main product (Fig. 6, Fig. 7), originate from stretching vibrations of $\mathrm{NH}\left(3000-3400 \mathrm{~cm}^{-1}\right)$ and BH ( $2150-2400 \mathrm{~cm}^{-1}$ ) groups. They are accompanied by bands coming from deformation vibrations of $\mathrm{NH}_{\mathrm{x}}$ moieties (1400-1600 $\mathrm{cm}^{-1}$ ) as typical of $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts and by BN stretching. $\mathrm{BH}_{\mathrm{x}}$ deformation modes fall below $1350 \mathrm{~cm}^{-1}$.

Aside from the bands typical for $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts, the NH stretching region of Raman spectrum (Fig. 7) contains a relatively low frequency band (peaking at $3041 \mathrm{~cm}^{-1}$ ) originating from ammonium cations. The ammonium cations are known to give strong Raman at much lower energies than the $\left[\mathrm{NH}_{2}\right]$ and [ $\mathrm{NH}_{3}$ ] groups, e.g. ammonium chloride gives a single band at $3052 \mathrm{~cm}^{-1},{ }^{30}$ while ammonium borohydride yields two bands at somewhat higher energies of $3118 \mathrm{~cm}^{-1}$ and $3178 \mathrm{~cm}^{-1} .4,31$

In the higher energy part of NH stretching region, in both FTIR and Raman spectra, we observe at least 6 distinct bands, four of which ( $3306 \mathrm{~cm}^{-1}, 3288 \mathrm{~cm}^{-1}, 3259 \mathrm{~cm}^{-1}, 3239 \mathrm{~cm}^{-1}$ in IR; $3307 \mathrm{~cm}^{-1}, 3288 \mathrm{~cm}^{-1}, 3260 \mathrm{~cm}^{-1}, 3240 \mathrm{~cm}^{-1}$ in Raman) form a doublet of doublets seen for heavy alkali metal $M$ (B3N2) salts; it is characteristic for $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts that that the higher energy doublet is more intense in FTIR spectra, while the lowerwavenumber one is stronger in Raman spectra. In contrast, the lower energy one is more intensive in Raman spectra. ${ }^{21}$ The presence of such doublets is caused by Davydov splitting, ${ }^{32}$ i.e. the interaction of $\left[\mathrm{NH}_{2}\right]$ groups coexisting within one crystallographic unit cell (the resonance of the corresponding

Fig. 6. Comparison of FTIR absorption (top in each bracket) and Raman scattering (bottom in each bracket) spectra of the main product of the synthesis according to Eq. 1 (magenta) and the spectra of alkali metal $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts. Regions magnified in Fig. 7 (NH stretching and NH bending) are marked with grey fields.
oscillators removing their degeneration). A similar split of NH band was observed in the spectra of $\mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2)$ and $\mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2)$, which contain gauche-form of (B3N2)-- anions, unlike the lighter analogues featuring straight anions and not showing Davidov
split. ${ }^{21}$ The split observed here equals $\pm 9 \mathrm{~cm}^{-1}$, which is intermediate between those of $\pm 4 \mathrm{~cm}^{-1}$ and $\pm 14 \mathrm{~cm}^{-1}$ seen for $\mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2)$ and $\mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2)$, respectively. ${ }^{21}$

Two remaining bands observed in NH stretching region ( $3224 \mathrm{~cm}^{-1}$ and $3268 \mathrm{~cm}^{-1}$ in IR), are weaker than the doublets of doublets, and they must originate from vibrations of terminal $\left[\mathrm{NH}_{3}\right]$ groups of B3N3. Indeed, they fall in a spectral region typical for terminal $\left[\mathrm{NH}_{3}\right]$ groups of ammonia borane (3196 $\mathrm{cm}^{-1}, 3253 \mathrm{~cm}^{-1}$ and $3311 \mathrm{~cm}^{-1}$ ). Naturally, it is expected that signals originating from the terminal $\left[\mathrm{NH}_{3}\right]$ of B3N3 are weaker than those from more numerous $\left[\mathrm{NH}_{2}\right]$ groups present in both ( $\mathrm{NH}_{4}$ )(B3N2) and B3N3.

The region of the IR absorption spectrum associated with deformations of the $\mathrm{NH}_{x}$ moieties (Figure 7) is consistent with these conclusions. One can clearly distinguish signals at $c a$. $1530-1600 \mathrm{~cm}^{-1}$, typical for $\left[\mathrm{NH}_{2}\right]$ and $\left[\mathrm{NH}_{3}\right]$ groups, ${ }^{21}$ from the signals at $c a .1250-1500 \mathrm{~cm}^{-1}$, characteristic for ammonium cations (cf. $1402 \mathrm{~cm}^{-1}$ for $\mathrm{NH}_{4} \mathrm{Cl}$ ). ${ }^{33} \mathrm{It}$ is worth to notice, that the IR spectra in the $1350-1500 \mathrm{~cm}^{-1}$ region show five bands ( 1374 $\mathrm{cm}^{-1}, 1392 \mathrm{~cm}^{-1}, 1415 \mathrm{~cm}^{-1}, 1427 \mathrm{~cm}^{-1}, 1479 \mathrm{~cm}^{-1}$ ), and this agrees with the number of deformation modes expected for $\mathrm{NH}_{4}{ }^{+}$cation in a low-symmetry environment.

The spectroscopic analysis clearly shows that both $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ and B3N3 moieties constitute the main product, thus confirming the reactions according to Eq. 1 and Eq. 2.

### 2.4 Crystal structure of the side product

The chemical composition of the side product of metathesis was confirmed by single crystal x-ray diffraction measurements (cf. ESI). This compound contains protonated Verkade's base cations and tetraphenylborate anions, $(\mathrm{VBH})\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]$, proving successful ion exchange in reaction according to Eq. 1. The compound crystallises in $P \overline{1}$ space group with the constituent

Fig. 7. Comparison of NH stretching ( $3000-3400 \mathrm{~cm}^{-1}$ ) and NH bending (1300-1700 cm ${ }^{-1}$ ) regions of FTIR absorption (top in each bracket) and Raman scattering (bottom in each bracket) spectra of the main product of the synthesis according to Eq. 1 (magenta) and alkali metal M(B3N2) salts. Full spectra presented in Fig. 6.
ions of different polarities showing no significant interactions, as expected for large ions with small charge smeared over the entire ion.

### 2.5 Crystal structure of the main product

As we could not obtain a single crystal of the main product, we were forced to use powder X-ray diffraction (PXRD), supported by DFT calculations and the results of spectroscopic analysis described above.

Indexing of the PXRD pattern leads to a $P 2_{1} / c$ unit cell with the refined lattice parameters of: $a=13.391(10) \AA, b=13.195(8)$ $\AA$ A, $c=17.822(12) \AA, \beta=125.86(4)^{\circ}$ and $V=2552(3) \AA^{3}$. Assuming $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ as a product, such unit cell volume would suggest $Z=16$ (multiplicity of the general atomic position) and $V / Z=$ $159.5 \AA^{3}$. However, this $V / Z$ value is too small as the values for $K$ and Rb analogues are larger (167.7 $\AA^{3}$ and $174.3 \AA^{3}$ respectively) ${ }^{21}$ while the size of $\mathrm{NH}_{4}{ }^{+}$falls between these two alkali metal cations. Somewhat The smaller than expected V/Z volume suggests that the crystalline phase should contain also the partially dehydrogenated molecules of the product of condensation presented in Eq. 2.

To test such scenario, structural models were derived for $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2), \mathrm{B} 3 \mathrm{~N} 3$ and the $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ cocrystal with the components in the $1: 3$ molar ratio as indicated by NMR data. Initial positions of heavy atoms came from simulated annealing using the experimental diffraction data. The models were then fully optimized using periodic DFT calculations (Table 2 and SI ). The theoretical unit cell volume calculated for $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ is significantly larger than those for the models containing B3N3 moieties and the latter are only 4.0-4.5\% larger than the experimental value. This degree of overestimation is rather typical for the GGA calculations.
Importantly, the closest $\mathrm{H} \cdots \mathrm{H}$ contacts in the optimized structure of $\left(\mathrm{NH}_{4}\right)(B 3 N 2)$ remain unreasonably short (1.40 Å), and outside the distribution observed experimentally for the dihydrogen bonds (usually $>1.80 \AA$ ), Fig. 9. This reconfirms that the main product is not a pure $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$. The minimum $\mathrm{H} \cdots \mathrm{H}$ contacts in the optimized crystal structures containing B3N3 are significantly longer (1.60-1.68 Å), and closer to typical values for very strong dihydrogen interactions. Therefore, we have used a theoretical model of the ( $\mathrm{NH}_{4}$ )(B3N2)•3(B3N3) cocrystal to refine its crystal structure using the best experimental dataset, Figure 8 and Figure S9.3 (SI).

The obtained structural model of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ contains four formula units in the unit cell $(Z=4)$ with one asymmetric unit ( $Z^{\prime}=1$ ).

Fig. 8. Visualisation of the unit cell (left) and the asymmetric unit (right) of the crystal structure of the cocrystal comprising one unit of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ salt and three independent units of B3N3 molecules. Atom code: nitrogen - blue, boron - green, hydrogen - white.

Fig. 9. Distribution of $\mathrm{H} \cdots \mathrm{H}$ distances in $-\mathrm{B}-\mathrm{H} \cdots \mathrm{H}-\mathrm{N}-$ moieties found in CSD database search (accessed by the end of 2020). The distances <2.8 $\AA$ were found for 865 crystal structures. Note the distances: $2.4 \AA$ (double H van der Waals radius) ${ }^{1}$ and $1.92 \AA$ A present in the structure.

The structure is stabilized by strong dihydrogen interactions. Two B3N3 chains adopt gauche geometry, and resemble the B3N2 anions in the heavier M(B3N2) salts, $M=R b, C s .{ }^{21}$ The third B3N3 moiety and (B3N2)- anion are more straight, closer to the geometry of anionic moieties in the light $M(B 3 N 2)$ salts, $\mathrm{M}=\mathrm{Li}-\mathrm{K} . \mathrm{.}^{21,22}$ The B-N distances of 1.56(2)-1.58(2) Å remain within range observed in other compounds from this group.
Further improvements of our preliminary experimental structure model, and in particular positions of hydrogen atoms, would require application of neutron diffraction methods, and is beyond the scope of this work.

### 2.6 Thermal decomposition

The theoretical gravimetric hydrogen content of the 1:3 cocrystals is very large, $16.4 \%$. We have studied thermal decomposition of this new compound to assess its hydrogen storage properties. In Fig. 10 we present the results of a simultaneous thermogravimetric and calorimetric analysis of the main product together with gas evolution curves (hydrogen, ammonia, diborane, borazine) acquired in mass spectrometry experiment of the evolved gases.

The main product is thermally stable below $50^{\circ} \mathrm{C}$. At higher temperatures, one can observe a multistep exothermic decomposition preceded by an endothermic process. During decomposition, a mixture of gases containing borazine, hydrogen, diborane and ammonia is being evolved. Close analysis of TGA/DSC/MS curves suggests that decomposition proceeds in at least 3 steps below $200^{\circ} \mathrm{C}$, but each of them seems to have a similar profile of evolved gases. Interestingly, borazine is the main gaseous product of thermal decomposition, just as in the case of $\mathrm{NH}_{3} \mathrm{BH}_{3},{ }^{6}$ but dissimilarly to alkali metal M (B3N2) salts. ${ }^{21,22}$ Facile evolution of borazine

Table 2. Summary of the DFT results. Minimum H...H distance is given for fully optimized unit cell and those which lattice vectors were fixed at experimental values. The model of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ refined to the experimental XRD data is added for comparison.

[^1]

Fig. 10. Thermogravimetric (TG) and calorimetric (DCS) profiles of the main product set together with MS profiles of the evolved volatile products: hydrogen ( $\mathrm{m} / \mathrm{z}=2$ ), ammonia ( $\mathrm{m} / \mathrm{z}=16$ ), diborane ( $\mathrm{m} / \mathrm{z}=27$ ), borazine ( $\mathrm{m} / \mathrm{z}=80$ ). Scanning rate: $1 \mathrm{~K} / \mathrm{min}$ (black), $5 \mathrm{~K} / \mathrm{min}$ (magenta).
may be related to stoichiometry of two components of the main product. ( $\mathrm{NH}_{4}$ )(B3N2) and B3N3, both contain 3 boron atoms and 3 nitrogen atoms, just like borazine molecules. Dehydrogenation of B 3 N 3 molecule proceeds with formation of a new $\mathrm{B}-\mathrm{N}$ bond at $\left[\mathrm{BH}_{3}\right]$ and $\left[\mathrm{NH}_{3}\right]$ terminals according to Eq. 4. This reaction was also proposed as the final step of borazine evolution during thermal decomposition of ammonia borane. ${ }^{34}$ Formation of pseudo-aromatic borazine is accompanied by dehydrogenation of the elusive head-to-tail cyclohexane-like intermediates, according to Equation 4.
$\mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3} \rightarrow \mathrm{c}-\mathrm{N}_{3} \mathrm{~B}_{3} \mathrm{H}_{12}+\mathrm{H}_{2} \rightarrow \mathrm{~B}_{3} \mathrm{~N}_{3} \mathrm{H}_{6}+4 \mathrm{H}_{2} \uparrow$ (4)
We also observed the formation of $\mathrm{B}_{2} \mathrm{H}_{6}$ and $\mathrm{NH}_{3}$, similarly as in decomposition of $\mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2),{ }^{21,22} \mathrm{~K}(\mathrm{~B} 3 \mathrm{~N} 2),{ }^{21} \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2)^{21}$ and $\mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2),{ }^{21}$ which come from fragmentation of (B3N2)- anions.

As mentioned above, the thermal decomposition of the main product is preceded by an endothermic process. Analogies to ammonia borane ${ }^{6}$ and amidoboranes ${ }^{10}$ might suggest melting of the sample. However, direct visual observations ruled out this possibility. Endothermic event is related either to an intermolecular reorganization or a structural phase transition.

Depending on the heating rate, decomposition temperature reaches the fastest rate at $\mathrm{ca} .145^{\circ} \mathrm{C}$ ca. $152^{\circ} \mathrm{C}$ for $1 \mathrm{~K} / \mathrm{min}$ and $5 \mathrm{~K} / \mathrm{min}$ scans, respectively. The observed mass loss upon thermal decomposition in the range up to $200^{\circ} \mathrm{C}$, equals $c a .45 \%$ and surpasses those of alkali metal $M$ (B3N2) salts ${ }^{21}$ and parent ammonia borane. ${ }^{6}$ Such large observed mass loss may be attributed to the evolution of borazine and other volatiles. The
solid residue is amorphous, and consists of boron nitride and polymeric $\mathrm{B}_{\mathrm{X}} \mathrm{N}_{Y} \mathrm{H}_{Z}$ phases as deduced from FTIR analysis (cf. ESI).

The observations discussed above lead to the following overall equations describing thermal decomposition of the two components of the main product:

$$
\begin{align*}
& \left(\mathrm{NH}_{4}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right) \rightarrow{ }^{1} /{ }_{6} \mathrm{~B}_{3} \mathrm{~N}_{3} \mathrm{H}_{6} \uparrow+ \\
& \quad+{ }^{1} /{ }_{4} \mathrm{~B}_{2} \mathrm{H}_{6} \uparrow+{ }^{1} / 4 \mathrm{NH}_{4} \uparrow+5 \mathrm{H}_{2} \uparrow+1 / \mathrm{n}(\mathrm{BHNH})_{\mathrm{n}}+\mathrm{BN}  \tag{5}\\
& \mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3} \rightarrow{ }^{1} /{ }_{6} \mathrm{~B}_{3} \mathrm{~N}_{3} \mathrm{H}_{6} \uparrow+ \\
& \quad+{ }^{1} /{ }_{4} \mathrm{~B}_{2} \mathrm{H}_{6} \uparrow+{ }^{1} / 4 \mathrm{NH}_{4} \uparrow+4 \mathrm{H}_{2} \uparrow+1 / \mathrm{n}(\mathrm{BHNH})_{\mathrm{n}}+\mathrm{BN} \tag{6}
\end{align*}
$$

Theoretical mass loss of Eq. 5 and Eq. 6 equal 43\% and 42\%, respectively, which reasonably agree with the observed experimental mass loss of $c a .45 \%$.

## Conclusions

Synthesis of hydrogen-rich $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ salt was attempted in metathetic approach using precursors which contained weakly coordinating ions. The obtained product, however, corresponds to a mixture of ionic $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ and neutral B3N3 forming cocrystals in molar ratio of $1: 3$. Based on available ${ }^{11} \mathrm{~B}$ NMR data, the main product was found to be very similar to the samples reported earlier by Ewing et al. ${ }^{19}$ as B3N3.

The compound crystallises in $P 2_{1} / c$ unit cell with the lattice parameters of: $a=13.401(11) \AA \AA, b=13.196(8) \AA \AA, c=17.828(12)$ $\AA, \beta=128.83(4)^{\circ}, V=2556(3) \AA^{3}$ and $Z=16$. The expected side product of a metathetic reaction, (VBH) $\left[B\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]$, crystallises in $P \overline{1}$ unit cell with the lattice parameters of $a=11.7376(3) \AA, b=$ 19.5388(5) $\AA, c=20.5479(4) \AA, \alpha=61.751(2)^{\circ}, \beta=73.618(2)^{\circ}, \gamma$ $=89.605(2)^{\circ}, V=3937.71 \AA^{3}$ and $Z=4$.

Despite its high hydrogen content of $16.4 \%$, the new compound cannot act as a self-standing solid-state hydrogen reservoir as it decomposes via a set of exothermic events while evolving mixture of volatile gaseous products such as borazine, diborane and ammonia, aside from hydrogen. However, it is possible that templating our product in porous matrixes could result in substantial improvement of purity of the evolved hydrogen, similarly as it was observed for ammonia borane. ${ }^{35}$

## Experimental

Reagents: All operations were performed under inert Ar atmosphere inside gloveboxes, MBRAUN Labmaster DP or Vigor SG1200 ( $\left.\mathrm{O}_{2}, \mathrm{H}_{2} \mathrm{O}<1.0 \mathrm{ppm}\right)$. Commercially available reagents and solvents were used: $\mathrm{NH}_{3} \mathrm{BH}_{3}$ ( $98 \%$, JSC Aviabor), $\mathrm{NH}_{4} \mathrm{~B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}$ (99\%, Sigma-Aldrich (later denoted as SA), $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}$ ( $99 \%$, SA ), $\mathrm{CH}_{2} \mathrm{Cl}_{2} \quad(99 \%, \mathrm{SA})$. The synthesis of $\left(\mathrm{C}_{18} \mathrm{H}_{3} \mathrm{~N}_{4} \mathrm{PH}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)$ was performed according to the route described in our earlier paper. ${ }^{21}$ For NMR measurements we used THF-d8 (99.5 atom\% D, SA).

Infrared absorption spectroscopy: FTIR spectra were measured in the standard range of $400-4000 \mathrm{~cm}^{-1}$ using Fourier Transform IR spectrometer Vertex 80v from Bruker. Samples were examined using KBr pallets prepared using anhydrous KBr ( $99 \%, \mathrm{SA}$ ) additionally dried in $150^{\circ} \mathrm{C}$ for 24 h .

Raman spectroscopy: Raman scattering measurements were done using Raman microscopy setup from Jobin Yvon T64000 with Si CCD detector and Kr -Ar gas laser from

Spectraphysics. We used green 514.5 nm excitation line. For the measurements small doses of samples were placed in 0.5 mm thick quartz capillaries sealed under inert gas atmosphere.

Nuclear Magnetic Resonance: ${ }^{1} \mathrm{~B}$ NMR spectra with and without ${ }^{1} \mathrm{H}$ decoupling were obtained using Agilent 700 MHz spectrometer with Direct Drive 2 console and 5 mm roomtemperature broadband probe. We used deuterated tetrahydrofuran ( $\mathrm{d}_{8}-\mathrm{THF}$ ) as a solvent. The number of scans has been set to 256 , the interscan delay to 1 s and the acquisition time to 200 ms . The spectra were acquired at 25 C . The exponential apodization has been used during processing (line broadening of 5 Hz ).

Thermogravimetrical Analysis: Thermal decomposition was investigated using STA 410 thermal analyser from Netzsch, in the temperature range from $-10^{\circ} \mathrm{C}$ to $+200^{\circ} \mathrm{C}$. STA 449 allows simultaneous thermogravimetric analysis, differential scanning calorimetry and evolved gas analysis by means of mass spectrometry. The samples were loaded into alumina crucibles inside a glovebox. Helium was used as a carrier gas. Evolved gases were analysed with a QMS 403C Aëolos MS from PfeifferVacuum. Transfer line was preheated to $100^{\circ} \mathrm{C}$ to avoid condensation of residues.

Powder X-ray diffraction: PXRD measurements were conducted on samples sealed in 0.5 mm thick quartz capillaries under inert atmosphere. Two diffractometers were used: Panalytical X'Pert Pro with linear PIXcel Medipix2 detector (parallel beam; the CoK $\alpha_{12}$ radiation); and Bruker D8 Discover with 2D Vantec detector (parallel beam; the CuK $\alpha_{12}$ radiation).

Crystal structure solution of the main product: Diffraction signals have been indexed using $X$-cell ${ }^{36}$ and the initial structural model has been obtained using FOX software, ${ }^{37}$ while the Rietveld refinement has been performed in Jana2006. ${ }^{38}$ Pseudovoight functions with Berrar-Baldinozzi asymmetry have been used for modeling of diffraction profiles. The restraints were used during refinement for the $\mathrm{N}-\mathrm{H}$ and $\mathrm{B}-\mathrm{H}$ distances (at $0.900(10) \AA$ and $1.100(10) \AA$, respectively, Fig. S9.2), and the angles related to hydrogen atoms (to $109.47^{\circ}$ with tolerance of ca. $0.5^{\circ}$ ). The N-B distances were set to the value 1.57 (1) $\AA$. The atomic displacement parameters of $B$ and $N$ atoms were set equal, while those of H atoms were constrained according to the riding model. The bottom constraint of $1.91 \AA$ for H...H distances was applied. Further details on the crystal structure may be obtained from CCDC/FIZ Karlsruhe on quoting the CSD deposition No. 2193624.

Crystal structure solution of the side product: Crystal of the compound were covered with perfluorinated oil (Krytox 1531). Data collection and reduction was performed with Agilent Supernova X-ray diffractometer with $\mathrm{K} \alpha-\mathrm{Cu}$ radiation (microsource) with data reduction performed by CrysAlisPro software (v. 40.99). ${ }^{39}$ Structure solution: SHELXT, ${ }^{40}$ refinement against $F^{2}$ in Shelxl-2018, with ShelXle as GUI software. ${ }^{41}$ The disorder of the $-\mathrm{OC}\left(\mathrm{CF}_{3}\right)_{3}$ groups was resolved using DSR. ${ }^{42}$ Further details on the crystal structure may be obtained from CCDC/FIZ Karlsruhe on quoting the CSD deposition No. XXX.

Density Functional Theory (DFT) calculations were performed using CASTEP. ${ }^{43}$ Generalized Gradient Approximation (GGA) was used with PBE functional and

Tkatchenko-Scheffler dispersive correction. ${ }^{44}$ The cutoff value of 500 eV was applied to achieve good energy convergence. The density of the k-point grid was set below $0.1 \AA^{-1}$ and ultrasoft, generated on the fly pseudopotentials were used as they provide more accurate lattice parameters.

Graphical presentation of crystal structures has been performed with Vesta. ${ }^{45}$

## Contents:

1. Records of reports on novel amidoborane and $M(B 3 N 2)$ salts and related compounds:
2. Synthesis of $M(B 3 N 2)$ salts of the products obtained:
$\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3) \quad \mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2) \mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{NH}_{3} \mathrm{BH}_{3}$
3. Table of ${ }^{11} \mathrm{~B}$ NMR @ THF- $\mathrm{d}_{8}$ chemical shifts of $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts and ammonia borane:
$\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3) \quad \mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{NH}_{3} \mathrm{BH}_{3} \quad \mathrm{VBH}(\mathrm{B} 3 \mathrm{~N} 2)$
4. Table of bands appearing in the FTIR spectra of $M(B 3 N 2)$ salts and ammonia borane:
( $\mathrm{NH}_{4}$ )(B3N2)•3(B3N3) $\mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2) \mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2) \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{NH}_{3} \mathrm{BH}_{3}$
5. Table of bands appearing in the Raman spectra of $M(B 3 N 2)$ salts and ammonia borane:
$\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3) \mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2) \mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2) \mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{NH}_{3} \mathrm{BH}_{3}$
6. Comparison FTIR and Raman spectra of $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts:
$\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3) \quad \mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2) \mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2) \mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2) \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2) \mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2)$
7. Thermal decomposition (TGA curves) of $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts:
( $\mathrm{NH}_{4}$ )(B3N2)•3(B3N3) Li(B3N2) $\mathrm{Na}(\mathrm{B} 3 N 2) \quad \mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2)$
8. FTIR spectra of the products of thermal decomposition of $M(B 3 N 2)$ salts:
$\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3) \quad \mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2) \quad \mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2)$
9. Experimental crystal structure and Rietveld fit for $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ :
$\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$
10. Table with the closest $\mathrm{H} \cdots \mathrm{H}$ distances in the crystal structure of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ :
$\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$
11. Experimental and modelled NMR spectra for various possible compositions of the main product:
$\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3) \quad\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \quad(\mathrm{B} 3 \mathrm{~N} 3)$
12. Results of DFT optimisation of modelled crystal structures:
$\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3) \quad\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \quad(\mathrm{B} 3 \mathrm{~N} 3)$
13. Crystal structure (VBH) $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]$
(VBH) $\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]$

## 1. Records of reporting synthesis of novel amidoborane and $M(B 3 N 2)$ salts and related compounds:

Fig. S1.1. Hydrogen content of monometallic amidoboranes (black), bimetallic amidoboranes (grey), $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2$ ) salts (magenta) and as a function of reporting date. Hydrogen content of $\mathrm{NH}_{3} \mathrm{BH}_{3}(19.6 \%)$, polymeric $\left(\mathrm{NH}_{2} \mathrm{BH}_{2}\right)(14.0 \%)$ and DOE ultimate target ( $6.5 \%$ ) given as a reference. Reports and theses marked with hollow circles.

## 2. Synthesis of alkali metal M(B3N2) salts:

All operations were performed under inert Ar atmosphere inside gloveboxes, MBRAUN Labmaster DP or Vigor SG1200 ( $\mathrm{O}_{2}, \mathrm{H}_{2} \mathrm{O}<1.0 \mathrm{ppm}$ ). Commercially available reagents and solvents were used: $\mathrm{NH}_{3} \mathrm{BH}_{3}$ ( $98 \%$, JSC Aviabor), $\mathrm{NH}_{4} \mathrm{~B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}$ ( $99 \%$, Sigma-Aldrich (later denoted as SA ), $\mathrm{C}_{4} \mathrm{H}_{8} \mathrm{O}$ ( $99 \%, \mathrm{SA}$ ), $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ (99\%, SA).

Metathetic synthesis was performed using $\left(\mathrm{C}_{18} \mathrm{H}_{39} \mathrm{~N}_{4} \mathrm{PH}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)$ and $\mathrm{NH}_{4}\left[\mathrm{~B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]$ in anhydrous THF at room temperature under argon atmosphere:
$\left(\mathrm{C}_{18} \mathrm{H}_{39} \mathrm{~N}_{4} \mathrm{PH}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)+\mathrm{NH}_{4}\left[\mathrm{~B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right] \rightarrow\left(\mathrm{NH}_{4}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)+\left(\mathrm{C}_{18} \mathrm{H}_{39} \mathrm{~N}_{4} \mathrm{PH}\right)\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]$
A follow-up process of dehydrogenation of $\mathrm{NH}_{4}\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)$ occurs leading to neutral linear molecule $\mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}$ :

$$
\left(\mathrm{NH}_{4}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right) \rightarrow \mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}+\mathrm{H}_{2} \uparrow
$$

Obtained mixture of products was well soluble in THF. Side product $\left(\mathrm{C}_{18} \mathrm{H}_{39} \mathrm{~N}_{4} \mathrm{PH}\right)\left[\mathrm{B}\left(\mathrm{C}_{6} \mathrm{H}_{5}\right)_{4}\right]$ was precipitated by washing with anhydrous DCM.

The main product crystallises in $P 2_{1} / c$ unit cell with the lattice parameters of: $a=13.401(11) \AA$, $b=13.196(8) \AA, c=17.828(12) \AA, \beta=128.83(4)^{\circ}, V=2556(3) \AA^{3}$ and $Z=16$. The crystalline product contains two compounds: $\mathrm{NH}_{4}\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)$ and $\mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}$ in molar ratio 1:3. In the manuscript, the product is denoted as "main product" or " $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ ".

The synthesis of $\left(\mathrm{C}_{18} \mathrm{H}_{39} \mathrm{~N}_{4} \mathrm{PH}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)$ was performed according to the route described in our earlier paper (R. Owarzany, et al., Inorg. Chem. 55 (2016) 37/) in a direct reaction of Verkade's Base with 3 equivalents of ammonia borane in toluene at room temperature:

$$
\mathrm{C}_{18} \mathrm{H}_{39} \mathrm{~N}_{4} \mathrm{P}+3 \mathrm{NH}_{3} \mathrm{BH}_{3} \rightarrow\left(\mathrm{C}_{18} \mathrm{H}_{39} \mathrm{~N}_{4} \mathrm{PH}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)+\mathrm{H}_{2} \uparrow+\mathrm{NH}_{3} \uparrow
$$

Different route of metathetic synthesis between $\mathrm{Na}\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)$ and $\mathrm{NH}_{4} \mathrm{Cl}$ in glyme at room temperature for 24 hours was reported earlier (W. C. Ewing et al. Inorg. Chem. 52 (2013) 10690.), however, the authors were aiming $\mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}$ according to the following equation:

$$
\mathrm{Na}\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)+\mathrm{NH}_{4} \mathrm{Cl} \rightarrow \mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}+\mathrm{H}_{2} \uparrow+\mathrm{NaCl} \downarrow
$$

Judging from the comparison of NMR data presented by Ewing et al. to our own data we strongly believe that this process leads to $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ according to the following reaction equations:

$$
\begin{gathered}
\mathrm{Na}\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)+\mathrm{NH}_{4} \mathrm{Cl} \rightarrow\left(\mathrm{NH}_{4}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)+\mathrm{NaCl} \downarrow \\
\left(\mathrm{NH}_{4}\right)\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right) \rightarrow \mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}+\mathrm{H}_{2} \uparrow
\end{gathered}
$$

## 3. Table of ${ }^{11}$ B NMR @ THF- $d_{8}$ chemical shifts of $M(B 3 N 2)$ salts and ammonia borane:

Table S3. Chemical shifts, positions of multiplets, excitation frequencies and J-coupling values observed in ${ }^{11} \mathrm{~B}$ NMR spectra in deuterated THF solution ( $\delta$ [ppm]) of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ at room temperature. Results for ammonia borane [AB], precursor [ $\beta-\mathrm{VBH}(\mathrm{B} 3 \mathrm{~N} 2)]$ and alkali metal $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts: $[\mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2)$, $\mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2), \mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2), \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2), \mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2)]$ at RT are shown for comparison.

## 6. Comparison of FTIR and Raman spectra of alkali metal M(B3N2) salts:

FTIR and Raman spectra of $\mathrm{NH}_{4}(\mathrm{~B} 3 \mathrm{~N} 2) / 3(\mathrm{~B} 3 \mathrm{~N} 3)$ and alkali metal $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts: [Li(B3N2), $\mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2)$, $\mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2), \mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2), \mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2)]$. NH and BH stretching and NH bending regions highlighted and magnified in separate figures.

Fig. S6.1. Comparison of FTIR spectra of M(B3N2) salts.

Fig. S6.3. Comparison of NH and BH stretching and NH bending regions of FTIR spectra of $M(B 3 N 2)$ salts.

Fig. S6.2. Comparison of Raman spectra of $M(B 3 N 2)$ salts.

Fig. S6.4. Comparison of NH and BH stretching and NH bending regions of Raman spectra of $M(B 3 N 2)$ salts.

## 7. Thermal decomposition (TGA curves) of M(B3N2) salts:

The thermal decomposition of $\mathrm{NH}_{4}(\mathrm{~B} 3 \mathrm{~N} 2) / 3(\mathrm{~B} 3 \mathrm{~N} 3)$ and alkali metal $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts occurs at the temperature range of $120-180^{\circ} \mathrm{C}$.

Fig.S7.1. TGA/DSC experiments of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ with scanning rates ( $1 \mathrm{~K} / \mathrm{min}$-black, $5 \mathrm{~K} / \mathrm{min}$-grey).

Fig.S7.3. TGA/DSC experiments of Na (B3N2) sample with different scanning rates ( $1 \mathrm{~K} / \mathrm{min}$-black, $10 \mathrm{~K} / \mathrm{min}$-grey).

Fig.S7.5. TGA/DSC experiments of $\mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2)$ sample with different scanning rates ( $1 \mathrm{~K} / \mathrm{min}$-black, $10 \mathrm{~K} / \mathrm{min}$-grey).

Fig.S7.2. TGA/DSC experiments of $\mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2)$ sample with different scanning rates ( $1 \mathrm{~K} / \mathrm{min}$-black, $10 \mathrm{~K} / \mathrm{min}$-grey).

Fig.S7.4. TGA/DSC experiments of $\mathrm{K}(\mathrm{B} 3 \mathrm{~N} 2)$ sample with different scanning rates ( $1 \mathrm{~K} / \mathrm{min}$-black, $10 \mathrm{~K} / \mathrm{min}$-grey).

Fig.S7.6. TGA/DSC experiments of $\mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2)$ sample with different scanning rates ( $1 \mathrm{~K} / \mathrm{min}$-black, $10 \mathrm{~K} / \mathrm{min}$-grey).

## 8. FTIR spectra of the products of thermal decomposition of M(B3N2) salts:

The thermal decomposition of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ leads to formation of boron nitride while decomposition of alkali metal $\mathrm{M}(\mathrm{B} 3 \mathrm{~N} 2)$ salts leads to formation of respective borohydrides.

Fig. S8.1. FTIR spectra of the product of thermal decomposition of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ sample.

Fig. S8.3. FTIR spectra of the product of thermal decomposition of $\mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2)$ sample.

Fig. S8.5. FTIR spectra of the product of thermal decomposition of $\mathrm{Rb}(\mathrm{B} 3 \mathrm{~N} 2)$ sample.

Fig. S8.2. FTIR spectra of the product of thermal decomposition of $\mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2)$ sample.

Fig. S8.4. FTIR spectra of the product of thermal decomposition of $K(B 3 N 2)$ sample.

Fig. S8.6. FTIR spectra of the product of thermal decomposition of $\mathrm{Cs}(\mathrm{B} 3 \mathrm{~N} 2)$ sample.

## 9. Experimental crystal structure and Rietveld fit for ( $\mathrm{NH}_{4}$ )(B3N2)•3(B3N3):

Fig. S9.1. Visualisation of the unit cell and formula unit of the main product: $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$

Fig. S9.2. Distribution of $\mathrm{N}-\mathrm{H}$ and $\mathrm{B}-\mathrm{H}$ distances in systems comprising both $\left[\mathrm{NH}_{\mathrm{x}}\right]$ and $\left[\mathrm{BH}_{\mathrm{x}}\right]$ groups found in structures in CSD database. Value of $\mathrm{N}-\mathrm{H}$ and $\mathrm{B}-\mathrm{H}$ distances in $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ marked with a dot.

Fig. S9.3. Rietveld analysis of ( $\mathrm{NH}_{4}$ )(B3N2)/3(B3N3) powder pattern. $\mathrm{CoK}_{\alpha 1,2}, \lambda=1.78901 \AA$.
10. Table with the closest $\mathrm{H} \cdots \mathrm{H}$ distances in the crystal structure of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$ :

Table S10. List of the closest $\mathrm{H} \cdots \mathrm{H}$ distances in experimental crystal structure of $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$. Listed only strong dihydrogen bonds, < 2 Å.

11. Experimental and modelled NMR spectra for various possible compositions of the main product: NMR spectra were simulated for various discussed possible compositions of the main product to ease visual examination of the experimental spectra obtained by us and reported earlier by Ewing et al., Inorganic Chemistry 52 (2013) 10690.

Fig. S11.1. Comparison of the experimental ${ }^{11} \mathrm{~B}$ NMR spectra obtained here and reported by Ewing et al. (Inorganic Chemistry 52 (2013) 10690) with spectra simulated for various possible compositions of the main product: $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3),\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ and (B3N3).

Fig. S11.2. Comparison of the experimental ${ }^{11} \mathrm{~B}\left\{{ }^{1} \mathrm{H}\right\}$ NMR spectra obtained here and reported by Ewing et al. (Inorganic Chemistry 52 (2013) 10690) with spectra simulated for various possible compositions of the main product: $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) \cdot 3(\mathrm{~B} 3 \mathrm{~N} 3)$, $\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2)$ and (B3N3).

## 12. Results of DFT optimisation of modelled crystal structures:

$\mathrm{NH}_{4}\left(\mathrm{BH}_{3} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right) \cdot 3\left(\mathrm{NH}_{3} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{2} \mathrm{NH}_{2} \mathrm{BH}_{3}\right)$, unit cell optimised

    $04 \alpha$-LiAB (13.7\%), $\mathrm{NaAB}(9.5 \%), \mathrm{KAB}(7.3 \%), \mathrm{Mg}(\mathrm{AB})_{2}(12.0 \%), \mathrm{Zn}(\mathrm{AB})_{2}(8.1 \%)-\mathrm{A}$. L. DeGraffenreid, Ph.D. Thesis, Ohio State University, 1995.
    $05 \alpha$-LiAB (13.7\%) - A. G. Myers, et al., Tetrahedron Lett. 37 (1996) 3623-3626.
    $06 \alpha-\operatorname{LiAB}(13.70 \%), \mathrm{NaAB}(9.54 \%)-Z$. Xiong, et al., Nature Mater. 7 (2008) 138-141.
    $07 \mathrm{Ca}(\mathrm{AB})_{2}(10.10 \%)$ - J. Spielmann, et al., Angew. Chem. Int. Ed. 47 (2008) 6290-6295.
    $08 \operatorname{Sr}(A B)_{2}$ (6.84\%) - Q. Zhang, et al., J. Phys. Chem. C 114 (2010) 1709-1714.
    $09 \beta$-LiAB (13.70\%) - C. Wu, et al., Inorg. Chem. 49 (2010) 4319-4323.
    $\mathrm{Y}(\mathrm{AB})_{3}(8.47 \%)$ - R. V. Genova, et al., J. Alloys. Comp. 499 (2010) 144-148.
    $\mathrm{Al}(\mathrm{AB})_{3}(12.97 \%)-\mathrm{M}$. F. Hawthorne, et al., Final Report, University of Missouri, 2010.
    KAB (7.31\%) - H. V. K. Diyabalanage, et al. J. Am. Chem. Soc. 132 (2010) 11836-11837.
    $\mathrm{Mg}(\mathrm{AB})_{2}(12.00 \%)$ - J. Luo, J. et al., Energy Environ. Sci. 6 (2013) 1018-1025.
    $\mathrm{Zn}(\mathrm{AB})_{2}(8.06 \%)$ - R. Owarzany, M.Sc. Thesis, University of Warsaw, 2013.
    LT-RbAB (4.37\%), LT-CsAB (3.1\%) - I. V. Kazakov, et al., Polyhedron 127 (2017) 186-190.
    $\mathrm{Ba}(\mathrm{AB})_{2}(5.12 \%)$ - N. A. Shcherbina, et al., Rus. J. Gen. Chem. 87 (2017) 2875-2877.
    HT-RbAB (4.37\%), HT-CsAB (3.1\%) - R. Owarzany, et al., Dalton Trans. 46 (2017) 16315-16320.
    $\mathrm{Na}_{2} \mathrm{Mg}(\mathrm{AB})_{4}$ (10.63\%) - H. Wu, et al., Chem. Commun. 47 (2011) 4102-4104.
    $\mathrm{NaMg}(\mathrm{AB})_{3}(11.05 \%)-\mathrm{X}$. Kang, et al., Dalton Trans. 40 (2011) 3799-3801.
    $\mathrm{LiNa}(\mathrm{AB})_{2}$ (11.24\%) - K. J. Fijalkowski, et al., Dalton Trans. 40 (2011) 4407-4413.
    $\mathrm{KMg}(\mathrm{AB})_{3}(9.88 \%), \mathrm{RbMg}(\mathrm{AB})_{3}(7.58 \%)-X$. Kang, et al., Int. J. Hydrog. Energy 37 (2012) 4259-4266.
    $\mathrm{K}_{2} \mathrm{Mg}(\mathrm{AB})_{4}(9.08 \%)$ - Y. S. Chua, et al., Chem. Mater. 24 (2012) 3574-3581.
    $\mathrm{LiAl}(\mathrm{AB})_{4}(13.15 \%)$ - G. Xia et al. Mater. Chem. A. 1 (2013) 1810-1820.
    $\mathrm{NaAl}(\mathrm{AB})_{4}(11.9 \%)$ - I. Dovgaliuk et al., Chem. Eur. J. 21 (2015) 14562-14570
    $\mathrm{Li}_{2} \mathrm{Mg}(\mathrm{AB})_{4}(12.79 \%)-\mathrm{N}$. Biliškov et al., Chem. Eur. J. 23 (2017) 16274-16282.
    KAl(AB) ${ }_{4}(10.87 \%)$ - K. T. Møller, et al., Int. J. Hydrog. Energy 43 (2018) 311-321.
    $\mathrm{Li}_{2} \mathrm{Ca}(\mathrm{AB})_{4}(11.63 \%), \mathrm{Na}_{2} \mathrm{Ca}(\mathrm{AB})_{4}(9.81 \%)$ - I. Milanovic, et al., ACS Sustainable Chem. Eng. 9 (2021) 2089-2099.
    Li(B3N2) (15.22\%), Na(B3N2) (12.66\%) - I. C. Evans, Ph.D. Thesis, University of Birmingham, 2011.
    Li(B3N2) (15.22\%) - K. R. Ryan, Ph.D. Thesis, University of Oxford, 2011.
    $\alpha-V B(B 3 N 2)(3.15 \%)-W . C . E w i n g$, et al., J. Am. Chem. Soc. 133 (2011) 17093-17099.
    $\mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2)(12.66 \%),\left(\mathrm{NH}_{4}\right)(\mathrm{B} 3 \mathrm{~N} 2) / 3(\mathrm{~B} 3 \mathrm{~N} 3)(16.4 \%)-\mathrm{W} . \mathrm{C}$. Ewing, et al., Inorg. Chem. 52 (2013) 10690-10697.
    $\mathrm{Li}(\mathrm{B} 3 \mathrm{~N} 2)(15.22 \%), \mathrm{Na}(\mathrm{B} 3 \mathrm{~N} 2)(12.66 \%)$ - K. J. Fijalkowski, et al., Phys. Chem. Chem. Phys. 16 (2014) 23340-23346.
    K(B3N2) (10.83\%), Rb(B3N2) (7.65\%), Cs(B3N2) (5.89\%), $\beta-\mathrm{VB}(\mathrm{B} 3 N 2)(3.15 \%)-\mathrm{R}$. Owarzany, et al., Inorg. Chem. 55 (2016) 37.
    ( $\left.\mathrm{Bu}_{4} \mathrm{~N}\right)(\mathrm{B} 3 \mathrm{~N} 2)(3.80 \%),\left(\mathrm{Et}_{4} \mathrm{~N}\right)(\mathrm{B} 3 \mathrm{~N} 2)(6.00 \%),\left[\mathrm{C}\left(\mathrm{N}_{3} \mathrm{H}_{6}\right)\right](\mathrm{B} 3 \mathrm{~N} 2)(13.70 \%),\left[\mathrm{C}\left(\mathrm{N}_{3} \mathrm{H}_{5} \mathrm{CH}_{3}\right)\right](\mathrm{B} 3 \mathrm{~N} 2)(11.7 \%)-\mathrm{X} . \mathrm{M}$. Chen, Chem Asian J. 16 (2021) 1-7.
    ( $\mathrm{NH}_{4}$ ) $(\mathrm{B} 3 \mathrm{~N} 2) / 3(\mathrm{~B} 3 \mathrm{~N} 3)(16.4 \%)$ - this study
