Running head: TMEM184B in hippocampal synaptic gene expression

Keywords: TMEM184B, hippocampus, RNAseq, synapse, Alzheimer's Disease

Abstract

In Alzheimer's Disease (AD) and other dementias, hippocampal synaptic dysfunction and loss contribute to the progression of memory impairment. Recent analysis of human AD transcriptomes has provided a list of gene candidates that may serve as drivers of disease. One such candidate is the membrane protein TMEM184B. To evaluate whether TMEM184B contributes to neurological impairment, we asked whether loss of TMEM184B in mice causes gene expression or behavior alterations, focusing on the hippocampus. Because one major risk factor for AD is age, we compared young adult (5-month-old) and aged (15-month-old) wild type and *Tmem184b*-mutant mice to assess the dual contributions of age and genotype. TMEM184B loss altered expression of pre- and post-synaptic transcripts by 5 months and continued through 15 months, specifically affecting genes involved in synapse assembly and neural development. Wnt-activated enhancer elements were enriched among differentially expressed genes, suggesting an intersection with this pathway. Few differences existed between young adult and aged mutants, suggesting that transcriptional effects of TMEM184B loss are relatively constant. To understand how TMEM184B disruption may impact behaviors, we evaluated memory using the novel object recognition test and anxiety using the elevated plus maze. Young adult *Tmem184b*-mutant mice show normal object discrimination, suggesting a lack of memory impairment at this age. However, mutant mice showed decreased anxiety, a phenotype seen in neurodevelopmental disorders. Taken together, our data suggest that TMEM184B is required for proper synaptic gene expression and function but may not be causal for AD and related dementias.

Introduction

Alzheimer's Disease (AD) is a devastating neurodegenerative disease for which we have a paucity of treatment options. In 2022, it is estimated that 10.7% of adults over 65 have Alzheimer's-induced dementia [1]. The burden on patients, their families and health systems is expected to grow significantly in the next 20 years; this trend is already apparent [2].

Alzheimer's Disease causes the accumulation of amyloid beta plaques and neurofibrillary tangles in diverse regions of the brain [3]. Many clinical trials have focused on the depletion of amyloid as a key therapeutic strategy. However, trials in which amyloid plaques are successfully diminished have not produced a reduction or delay in cognitive impairment in trial participants [4]. This highlights the need for the identification of new targets that may contribute to early cognitive impairment and that may offer hope at alternative strategies for stopping the progression of Alzheimer's Disease.

Large-scale human genome-wide association and RNAseq analysis to identify network drivers of disease has yielded many plausible candidates that could contribute to AD [5–7]. With these candidates in hand, the task for the AD field now shifts to identifying which candidates cause bona fide alterations in relevant gene expression pathways or in behaviors associated with AD. Through a recent RNAseq analyses, the transmembrane protein TMEM184B was predicted as a candidate protein that could promote AD progression [8]. TMEM184B is a 7-pass transmembrane protein expressed broadly in the nervous system and is thought to play a role in neuronal excitability, synaptic structure, and expression of key developmental and adult pathways involved in neuronal differentiation [9, 10]. Using analysis of the ROSMAP and MAYO clinic human cohorts, *TMEM184B* was predicted to drive AD-associated gene expression patterns in the dorsolateral prefrontal cortex and temporal cortex, respectively [8]. However, knockdown of *TMEM184B* in human induced pluripotent stem cell-derived neurons did not directly affect Aβ levels [5], suggesting that this gene may play a more indirect role.

In this study we sought to directly test the hypothesis that TMEM184B regulates gene networks that could contribute to AD, using a mutant mouse model in which the *Tmem184b* gene is disrupted [11]. We compared how TMEM184B-regulated gene networks are influenced by aging, focusing on the hippocampus as a key location involved in memory. We identified impairments in pathways controlling synapse assembly and function in TMEM184B-deficient hippocampus. We also evaluated memory and anxiety behaviors in these mice. Our results identify a clear effect of TMEM184B on the expression of synaptic gene networks at both young adult and older ages. We also uncovered an unexpected effect of TMEM184B loss on anxiety behavior. However, at young adulthood TMEM184B mutant mice do not have impaired memory. Our work places TMEM184B into a gene regulatory network that could impact synaptic connectivity and influence cognitive function but whose loss likely does not precipitate memory impairment.

Materials and Methods

Animal Assurances

All animal experiments are approved by and were performed in accordance with the University of Arizona Institutional Animal Care and Use Committee (IACUC) Protocol 17-216.

Hippocampal RNA Isolation

Male and female mice were humanely euthanized with carbon dioxide, and hippocampi were removed within 10 minutes of euthanasia and immediately frozen for subsequent RNA isolation. Total RNA was extracted using Trizol (Invitrogen) using the manufacturer's protocol. Following initial quality check via Nanodrop analysis, total RNA samples were frozen and shipped to Novogene (Sacramento, CA) for sequencing. Quality control checks were done by Novogene to ensure that sequenced samples had high RNA quality. Sequencing was performed using paired end 150bp reads, 30 million reads/sample, on the Illumina platform. Raw reads data were provided by Novogene.

Data Processing and Statistical Analysis

Alignment to the mouse genome (mm10.0) was done using Salmon and run on the High Performance Computing cluster at the University of Arizona. Differential gene expression analysis was done using DESeq2 on Galaxy servers (http://usegalaxy.org). PCA plots were generated by Galaxy's DESeq2 default settings, or done in R (https://cran.r-project.org/) using the stats R package.

For GO analysis, Panther pathway analysis, and KEGG pathway analysis, ribosomal genes were manually removed from the lists prior to submission. GO analysis (http://geneontology.org/) was performed with a background list of genes consisting of the full list of mapped genes identified by pseudoalignment via the Salmon algorithm from the datasets used for each comparison. KEGG analysis was performed using Enrichr online tools (https://maayanlab.cloud/Enrichr/). Transcription factor binding analysis involved two Enrichr tools: ChEA (2016) and Transcription Factor Perturbations. For both analyses, adjusted P-values were exported and plotted in Graphpad Prism.

Data Visualization

Fold change values were imported into Cytoscape and mapped onto networks (Biogrid Protein-Protein interaction Network as derived from https://downloads.thebiogrid.org/ or GOCAM Gene Ontology network, as derived from https://github.com/geneontology/gocam-sif-pyexport). To create subnetworks for visualization, we first identified hub proteins that were themselves differentially expressed and also contained multiple differentially expressed genes in their nearest neighbors. Colorization of levels of fold change used a continuous scale from red to blue, with grey representing genes not differentially expressed in the comparison groups. For biological processes, the default color palette was changed such that darker blues are more significant adjusted P-values, while lighter greens to white are less significant.

Graphs were made in either R (ggplot2 package) or in Graphpad Prism. Venn diagrams were created using online tools available at the University of Gent, Belgium (https://bioinformatics.psb.ugent.be/webtools/Venn/).

Novel Object Recognition

Our protocol for novel object recognition was adapted from Leger et al. [12]. Eight to ten mice of each genotype were used for this study; these mice were 5-7 months old and were approximately sex balanced (50/50 or 60/40). Mice were acclimated to the testing room and to the experimenter for two sessions (two days). On day 3, mice were individually placed in an empty square chamber and allowed to explore for 5 minutes. Videos were recorded from above the box in ambient light and with the experimenter outside the room. On day 4 (training/association), mice were returned to the chamber to explore two identical objects for ten minutes. On day 5 (24 hours after the day 4 training trial), mice were returned to the chamber which contained one familiar object from the day before, along with one novel object. Ten minutes of object exposure was captured via video. Videos were analyzed offline in Ethovision. To quantify mouse behavior, we used a discrimination index, which is calculated as (total time at novel object – total time at familiar object) / (total object exploration time). Positive values indicate recognition of a novel object.

Elevated Plus Maze

Mice were placed at the distal end of a closed arm and allowed to walk on an elevated X-shaped platform (50cm from the ground, 35 cm arm length, made of gray non-reflective non-odorous poly-methyl methacrylate (PMMA)) for five minutes. Two of the arms of the platform are enclosed by walls, while two are open. The number of times a mouse enters the open or closed arms is recorded. The ratio of open vs. closed entries, and time spent in open versus closed arms, are calculated as an index of anxiety. Benchpads are used under the open arms to cushion any unexpected falls.

Results

TMEM184B promotes expression of synapse assembly genes in the mouse hippocampus.

TMEM184B expression is required for maintenance of synaptic structure at neuromuscular junctions in both mouse and fly. We wondered if this role would extend to the hippocampus, a center for learning and memory processing. TMEM184B is expressed in neuronal layers of the hippocampus, suggesting it may contribute here as well. We compared gene expression in the hippocampus in wild type and *Tmem184b* gene-trap mutant mice (which have less than 5% mRNA of *Tmem184b* remaining [10, 11]) at 5 months of age (Fig 1 and Supplementary File 1). Wild type mice showed high clustering in both principal components (Fig 1a), while mutant mice separated well from wild type mice in principal component 1 (PC1). In total, 1153 genes were differentially expressed in *Tmem184b*-mutant hippocampi (Fig 1b-c). When considering those genes with significant hippocampus expression, a group of developmentally important transcripts emerged including Shank1 (involved in post-synaptic density scaffolding), Neurexin 1 (involved in synaptic assembly and adhesion), and Somatostatin (a marker of subtypes of interneurons).

To evaluate the biological processes likely affected by TMEM184B in the hippocampus, we used gene ontology analysis to pinpoint processes with significant enrichment of differentially expressed genes (DEGs) in our dataset (Fig 1d). This showed a large predicted effect on synapse assembly and neural development. Other processes that may be affected in *Tmem184b*-mutant mice include memory/cognition, synapse function, behavior, and neuronal cell death. We performed pathway analysis on these data by querying the KEGG database (Fig 1e). This analysis identified many key pathways affecting both glutamatergic (excitatory) and GABAergic (inhibitory) synapses. Furthermore, it suggested that the pathways dysregulated in *Tmem184b*-mutants were enriched for those contributing to neurodegenerative diseases including Parkinson's disease and Alzheimer's Disease. Taken together, our analysis of

168 transcriptomic changes in *Tmem184b*-mutant hippocampus predicts significant dysregulation of
169 synapses that may be linked to neurological disease.
170
171 **Synaptic Protein-Protein Interaction Networks and Biological Processes rely on**
172 **TMEM184B for proper hippocampal expression.**
173 We sought to take a closer look at the relatedness of genes that were differentially
174 expressed in the pathways described above, specifically synapse assembly and neural
175 development. Using Cytoscape, we visualized our gene expression changes on the predicted
176 mouse protein-protein interaction network annotated by Biogrid (Fig 2-B). We noticed a
177 significant enrichment of altered transcripts of proteins that are predicted to interact with two key
178 neurodevelopmental proteins: Neurogenin3 and with Shank1. However, contrary to our
179 expectations, *Tmem184b*-mutant mice show upregulation of proteins in these networks (shown
180 in circles with pink and red shading). Neurogenin 3 is a transcription factor that promotes
181 dendritogenesis in cultured hippocampal neurons [13]. Shank1, along with its family members,
182 are critical scaffolds for postsynaptic density proteins and glutamate receptors, and they are
183 implicated in autism spectrum disorders [14, 15]. The upregulation of these proteins could be a
184 direct effect of TMEM184B or a compensatory effect following other synaptic disruptions; our
185 data does not distinguish between these possibilities. Nevertheless, the correct levels of these
186 factors are crucial for maintenance of proper circuit assembly and function; both up- and down-
187 regulation of both proteins is deleterious [13, 16].
188 In addition to mapping our data onto known protein-protein interactions, we also mapped
189 our data onto gene ontology networks and assessed which neuronal or synapse-related
190 processes were predicted to be altered by TMEM184B expression. The most differentially
191 expressed GO Biological Processes associated with synapses were in synaptic transmission
192 and plasticity. This prediction is consistent with data showing that TMEM184B mutation causes
193 hyperexcitability at glutamatergic synapses in *Drosophila* [9]. Within the search term “neuron”

these processes were enriched for neurogenesis and projection (axon/dendrite) development. Overall, our analysis suggests that TMEM184B maintains appropriate expression of interconnected networks of synaptic and neurodevelopmental genes in the hippocampus.

Analysis of Transcription Factors Upstream of Hippocampal Differentially Expressed Genes implicates Wnt signaling alterations.

To understand why loss of TMEM184B causes gene expression changes in the hippocampus at 5 months, we performed an *in silico* analysis to identify enriched transcription factor target genes in our DEGs using two platforms. In the first (ChEA 2016), we identified four transcription factors with enriched targets (DMRT1, RARB, ZFP281, and TCF7) (Fig 3A-B). DMRT1 is not expressed in the brain and so is unlikely to have an effect. ZFP281 is a transcriptional repressor that maintains the pluripotency of stem cell populations and is highly expressed. RARB, or retinoic acid receptor beta, is a steroid hormone receptor responsive to retinoic acid (RA) and plays roles in embryonic development. Disruptions to RARB lead to neurodevelopmental delay and are associated with autism spectrum disorder [17]. TCF7 is a canonical Wnt signaling pathway mediator [18]. In a separate analysis, we used the EnrichR platform to examine the overlap between DEGs from our data set with mouse transcription factor manipulations performed by others. We identified many transcription factors whose gene expression alterations significantly resemble that of *Tmem184b*-mutant hippocampus. Interestingly, multiple associations were identified with transcription factors known to promote Wnt signaling (NEUROD1, TCF3, PLAGL2) [19][20, 21]. This is consistent with prior work suggesting that Wnt pathway dysfunction could participate in TMEM184B-dependent phenotypes [10]. Wnt/β-catenin signaling is critical for hippocampal neurogenesis [22, 23], so this suggests that one effect of *Tmem184b* disruption may be loss of neurons. Other factors, such as NFIA, are known contributors to stem cell maintenance and proliferation. Adult neurogenesis in the hippocampus is required for long-term spatial memory in mice [24]. Taken

220 together, this analysis suggests a possible role for TMEM184B in the generation of hippocampal
221 neurons via promotion of Wnt pathway signaling.
222
223 **Identification of Common and Unique Aging Signatures in *Tmem184b*-mutant**
224 **hippocampus**
225 The biggest risk factor for the development of Alzheimer's Disease is advanced age. To
226 identify unique signatures of TMEM184B that may affect the aging brain, we compared genes
227 that were altered upon aging (15 months of age) in wild type mice with those in *Tmem184b*-
228 mutant mice. The *Tmem184b* transcript itself was not significantly altered across wild type
229 aging, although it was slightly reduced in older mice (log_2FC = -0.13; Adjusted P value = 0.074).
230 After filtering out ribosomal transcripts, a total of 2171 genes were significantly altered in
231 15-month-old *Tmem184b*-mutant mice compared to age-matched wild types (Supplementary
232 File 2). Of these, 222 transcripts were altered at both ages (Fig 4A-B and Supplementary File
233 3). We identified the most enriched processes in this group using gene ontology (Fig 4C-D).
234 This analysis confirmed the strong effects of TMEM184B loss on synaptic processes, including
235 postsynaptic density organization, glutamate receptor and neuroligin binding activity, and
236 synaptic plasticity. Interestingly, both young and aged TMEM184B mutant mice have a small but
237 significant upregulation of ApoE transcripts (log_2FC of 0.23 and 0.30, respectively). This
238 comparison confirms that, throughout aging, TMEM184B continues to influence synaptic gene
239 expression.
240 If we compare 5-month-old and 15-month-old mutant mice, very few genes are
241 significantly different (104 total) (Fig 4E and Supplementary File 4). In this group, no biological
242 pathways, molecular functions, or cellular components reached statistical significance (all had
243 adjusted p values > 0.05). This indicates that the changes that have occurred in TMEM184B
244 mutant mice primarily occur by 5 months, and gene expression is relatively constant beyond
245 that point. We used the Molecular Signatures database (MSigDB) to query whether alterations

in this small group of genes were similar to other published transcriptomic datasets. This analysis revealed that the most similar datasets are mouse models of neurological disease, including two Huntington's Disease models (R6/2 and Q175) and spinal cerebellar ataxia models caused by disruption of Ataxin-1 (Fig 4F). This suggests that the few genes that are altered by aging in TMEM184B mutants may affect similar pathways to those affected in HD and Ataxia.

Somatostatin, and other neuronal genes, are similarly regulated in both central and peripheral neurons

To evaluate common signatures of TMEM184B-dependent gene expression across disparate types of neurons, we compared the differentially expressed genes (adjusted $p < 0.05$) between our 5 month hippocampus data set and one we have previously reported from 6 month adult dorsal root ganglia [10]. Among differentially expressed genes, we identified 12 genes (including *Tmem184b* itself) that were similarly regulated (Fig 5 and Supplementary File 5). In many cases, the fold change in the hippocampus was somewhat less than that in the DRG, which could reflect a greater percentage of non-neuronal cells in the hippocampus that may dilute the overall fold change. Nevertheless, we noticed that Somatostatin, a neuropeptide used as a marker of GABAergic inhibitory interneurons in the hippocampus (but which marks excitatory, pruriceptive neurons in the DRG), was downregulated in both data sets, suggesting a common means of regulation in these two tissues. One common upregulated gene, Tsukushi (*Tsku*), is a negative regulator of the Wnt pathway [25]. Taken together with our earlier analyses, this again implicates a loss of Wnt signaling in TMEM184B-associated phenotypes. Finally, Bc1, a long non-coding RNA that is upregulated in TMEM184B-deficient neurons, has been shown to promote translation of amyloid precursor protein (APP) and cause spatial learning and memory defects [26].

TMEM184B loss does not affect spatial memory but alters anxiety behaviors in middle aged mice

Finally, we sought to evaluate how these gene expression changes in the hippocampus affect behaviors driven by this brain region, including anxiety and object-oriented memory. In prior work, we established that six-month-old *Tmem184b*-mutant mice show no deficiencies on the rotarod assay, but show difficulty in an inverted screen test, indicating that some sensorimotor impairment is present [10, 11]. Prior to performing memory assays, we first evaluated mobility of mice in an open field, using the same arena we planned to use for spatial memory testing. We did not observe any significant differences in mobility (total distance traveled) (Fig 6A), indicating that we could use this paradigm and arena for novel object recognition, a classical object-oriented memory paradigm. However, we did not see any difference between wild type and *Tmem184b*-mutant mice in their ability to recognize novel objects (both showed a positive discrimination index, indicating more time at the novel object) (Fig 6B). This indicates that at six months of age, TMEM184B loss does not alter memory.

Next, we evaluated anxiety using the elevated plus maze. Anxious mice spend more time in closed arms (with walls) than in open arms (without walls). Surprisingly, we identified a decreased anxiety overall in *Tmem184b*-mutant mice when compared to wild types. *Tmem184b*-mutant mice spent considerably more time in the open arms of the maze (Fig 6C). This indicates that TMEM184B promotes appropriate anxiety levels in the elevated plus maze assay.

Discussion

TMEM184B was predicted in human transcriptome analyses to be associated with deleterious gene expression that could drive the progression of Alzheimer's dementia [8]. Our experiments sought to evaluate this hypothesis using RNAseq analysis across aging in young

297 and aged *Tmem184b*-mutant and wild type mice. Our results show that TMEM184B has
298 significant effects on synaptic gene expression in the hippocampus in both young and old mice.
299 Alteration of post-synaptic density gene transcripts occurred in all of our pathway
300 analyses. Proteins in this group, such as SHANK1, SHANK3, and PSD95/DLG4 contribute to
301 the scaffolding of neurotransmitter receptors. Interestingly, transcripts of all three of these genes
302 are over-expressed in *Tmem184b*-mutant mice. This upregulation of mRNA could reflect a
303 compensation for presynaptic dysfunction, an inappropriate dendritic overgrowth, or a failure to
304 prune exuberant synapses. In fly models of mutation of the TMEM184B ortholog, *Tmep*, extra
305 active zones and synaptic release sites (boutons) are observed at neuromuscular junctions [9],
306 suggesting that additional synapses may be a common effect of TMEM184B disruption. Further
307 detailed analysis of hippocampal synaptic morphology and physiology will be necessary to
308 parse apart these possibilities.
309 Somatostatin (*Sst*), a common downregulated gene across both central and peripheral
310 TMEM184B-deficient data sets, plays many distinct roles in the nervous system. In dorsal root
311 ganglia, it is a neurotransmitter for a subset of itch-activated sensory neurons [27]. TMEM184B
312 loss in DRG neurons causes disruption of sensation of interleukin-31, a key cytokine involved in
313 atopic dermatitis (eczema) that is detected exclusively by SST+ neurons [27, 28]. In contrast, in
314 the dentate gyrus, somatostatin reduction occurs in genetic models of temporal lobe epilepsy
315 [29]. Reintroduction of SST in this model reverses the epileptic phenotypes, arguing for a causal
316 role in suppression of seizures. *Drosophila* models of TMEM184B deficiencies show ectopic
317 firing and elevated synaptic calcium, indicating a role in restraining excitability [9]. Thus,
318 phenotypes of SST and TMEM184B overlap substantially; our determination that TMEM184B
319 regulates *Sst* expression in multiple cell types could explain this concordance. It would be of
320 future interest to determine whether restoration of SST in TMEM184B mutant mice could restore
321 normal gene expression and/or behaviors.

Another common theme among our data is the connection between TMEM184B and Wnt pathway regulation. In our prior work, we showed that TMEM184B expression positively influences the expression of many Wnt signaling components, as well as their downstream targets, in developing somatosensory neurons [10]. In this work, we also find dysregulation of Wnt components in the hippocampus, including the loss of Wnt pathway targets as well as upregulation of Wnt pathway inhibitors such as Tsukushi. Wnt signaling deficiency contributes to AD phenotypes in mouse models [30], and it has also been identified as a key pathway altered in human AD samples [31]. While our data does not directly link TMEM184B to the development of AD pathology, it suggests that TMEM184B dysfunction disrupts synaptic gene regulatory networks and also influences expression of genes with more direct links to AD.

The mechanism of action of the TMEM184B protein is yet unknown. Clues to its role include localization to endosomes and synaptic vesicles, accumulation of multilamellar structures in mutant presynaptic terminals, and additional autophagosomes and lysosomes in skeletal muscle in its absence. Because Wnt signaling occurs within endosomes and contributes to dendritic growth, we hypothesize that a failure of Wnt signaling (perhaps due to a blockade in the endolysosomal pathway) may account for some of the phenotypes we observe.

While we did not complete an exhaustive behavioral analysis, we found that TMEM184B disruption causes reduced anxiety in the elevated plus maze paradigm. Reduced anxiety is seen in some models of neuroatypical development including autism spectrum disorders and in mice predisposed to depression [32, 33]. We speculate that TMEM184B loss may disrupt anxiety circuits to cause this phenotype.

We did not observe memory impairment when TMEM184B was disrupted in 6-month-old mice. It is still possible that older mice may show impairments. However, perhaps more likely, we suspect that TMEM184B disruption itself is not causative for memory loss. Instead, we hypothesize that compromising TMEM184B function, in the presence of other susceptibility loci, may increase the likelihood of developing dementia. Given its strong effects on synaptic gene

348 expression networks as well as the disruptions to synaptic morphology and function seen in
349 other studies, it will be of future interest to directly evaluate synaptic function via electrical
350 recording in the hippocampus and to evaluate its role in the context of mouse models of AD.
351
352 **Data Availability**
353 The data sets generated and analyzed in the current study have been deposited to NCBI
354 GEO at the following accession: GSE204831. All custom-written code in R for RNAseq analysis
355 is available at GitHub (https://github.com/eriklarsen4/ggplot-scripts.git and
356 https://github.com/martharcb/). Dorsal root ganglion data to which we compared our
357 hippocampal RNAseq data can be found on NCBI GEO (GSE154316).

Figure Legends:

Figure 1. TMEM184B-dependent gene expression alterations in the mouse hippocampus. **A**, Principal component analysis (PCA) of wild type and mutant samples taken at 5 months of age shows strong clustering of wild types (black circles), and loose clustering of mutant samples (green circles). **B**, volcano plot showing both up- and down-regulation of genes based on differential expression analysis. Purple indicates adjusted P-values of $p < 0.05$. **C**, MA-plot of base mean expression value versus Log_2(Fold Change) from DeSeq2. Red, Adjusted $p < 0.05$; blue, adujsted $p < 0.01$. Selected genes of interest are labeled. **D**, GO Biological Process Fold Enrichment (FE) scores of categories above 2.0 FE. Numbers indicate average FE; parentheses denote number of processes in that category. **E**, KEGG Pathways analysis (done using Enrichr). Top 10 pathways are shown, ranked by p-value.

Figure 2. TMEM184B loss disrupts key synaptic gene networks. A-B, mouse protein interaction networks as defined by BioGRID. Node color represents log_2 of fold change (darker red indicates higher over-expression in *Tmem184b*-mutant; blue shades indicate downregulation in *Tmem184b*-mutant). Circles indicate adjusted P-values where $p < 0.05$; rectangles indicate $p > 0.05$. Edge lengths have no significance. **C-D**, GO Biological Process network maps (from GoCAM) showing terms (gene sets) having significant alteration in *Tmem184b*-mutant mice versus controls. Darker blue indicates stronger fold change, while larger nodes indicate stronger significance (all nodes shown have Adjusted $p < 0.05$). Edge lengths have no significance. GO Biological Process terms disrupted in *Tmem184b*-mutant hippocampi identified with the search term “synapse” (in C) or “neuron” (in D).

Figure 3. Analysis of Transcription Factors Upstream of Hippocampal DEGs identifies Wnt pathway alterations. A, Chromatin Enrichment Analysis (ChEA) for mouse transcription

498 factors (TFs) with binding in promoters of differentially expressed genes from *Tmem184b*-
499 mutant hippocampi at 5 months of age. Shown are TFs for which enrichment scores were
500 statistically significant (Adjusted P < 0.05). **B**, Base mean expression in 5-month-old
501 hippocampus of each transcription factor in A, graphed against its adjusted P-value. **C**, top 10
502 mouse data sets from transcription-factor-manipulated genetic backgrounds that show
503 significant overlap with TMEM184B differentially expressed genes. Adjusted P values calculated
504 by Enrichr.
505
506 **Figure 4. Gene Expression Changes in 15-month *Tmem184b*-mutant vs wild type mice. A**,
507 MA-plot of gene expression changes between 15-month-old *Tmem184b*-mutant and wild type
508 hippocampus. Red dots show genes with adjusted p < 0.05, while blue dots show adjusted p <
509 0.01. **B**, Venn diagram showing overlap between 5-month and 15-month genotype-induced
510 changes. **C-D**, evaluation of enrichment among the 222 overlapping genes using gene ontology
511 for Biological Processes (C) and Cellular Components (D). Shown is Combined Score reported
512 by Enrichr. This score takes into account both P-value and Odds Ratio. Asterisks indicate level
513 of statistical significance (Adjusted P-value, **** <0.0001, *** < 0.001, ** < 0.01). **E**, Four-way
514 comparison of differentially expressed genes (no ribosomal gene filtering). **F**, gene set
515 categories identified by Molecular Signatures Database (MSigDB) among genes different
516 between 5- and 15-month *Tmem184b*-mutant mice. Abbreviations: HD, Huntingon's Disease
517 model mice; Oligo, oligodendrocytes; Ataxin, Ataxin-1 mutant mice. The full list of molecular
518 signatures is shown in Supplementary Table 5.
519
520 **Figure 5. TMEM184B similarly regulates somatostatin and other transcripts in both**
521 **central and peripheral neurons.** Data for DRG is available at NCBI GEO (NCBI GEO
522 GSM4668859) Log_2FC of genes identified in each data set (hippocampus, black bars; adult

DRG, grey bars). A full list of genes differentially regulated in both data sets can be found in Supplementary Table 6.

Figure 6. Memory and Anxiety Behaviors in *Tmem184b*-mutant mice. All graphs show mice of both sexes and are approximately sex balanced. **A**, Open field habituation over five minutes for mice 5-7 months of age. Total distance traveled in centimeters. WT, wild type, Mut, *Tmem184b*-gene trap mutant mice. **B**, Memory test at 24 hours using the novel object recognition task. Discrimination index is calculated as described in materials and methods. Each dot shows an individual mouse. N = 10 wild type and 8 mutant mice. **C**, measurement of anxiety using the elevated plus maze. For all graphs, statistical evaluation used unpaired t-test with Welch's correction. Numbers in bars (in A and C) indicate sample size. Error bars show standard error of the mean (SEM) for all panels.

Supplementary Material

Supplementary File F1. DESeq2 output of differential gene expression analysis between the hippocampi of 5-month-old *Tmem184b*-mutant mice and age-matched wild types.

Supplementary File F2. DESeq2 output of differential gene expression analysis between the hippocampi of 15-month-old *Tmem184b*-mutant mice and age-matched wild types.

Supplementary File F3. Differentially expressed genes in *Tmem184b*-mutant mice common to both the 5-month-old and 15-month-old comparison groups. Ribosomal transcripts have been omitted.

549 **Supplementary File F4.** DESeq2 output of differential gene expression analysis between the
550 hippocampi of 15-month-old *Tmem184b*-mutant mice and 5-month-old *Tmem184b*-mutant mice.
551
552 **Supplementary File F5.** Analysis of 104 differentially expressed genes across aging in
553 *Tmem184b*-mutant mice using the Molecular Signatures Database (MsigDB).
554
555 **Supplementary File F6.** All genes identified as differentially expressed in both adult dorsal root
556 ganglia and hippocampus of *Tmem184b*-mutant mice compared to wild type mice.
