We numerically investigate the optical characteristics of a metal-dielectric-metal (MDM) waveguide side-coupled with two identical multimode stub resonators. Double plasmon-induced transparency (PIT) peaks with narrow full width at half maximum (FWHM) and high quality factor (Q-factor) can be observed in this structure. The Q-factors of PIT peaks in two stub resonators system are larger than those in single stub resonator system. A multimode coupled-radiation oscillator theory (MC-ROT), which is derived from ROT, is proposed to analyze the spectral response in the multimode system for the first time. The analytical results are confirmed by the finite-difference time-domain (FDTD) simulation results. We can also find that the Q-factors of the two PIT peaks have an opposite evolution tendency with the change of the stubs parameters and the maximum can reach to 427. These results may provide some applications for ultrasensitive sensors, switches and efficient filters.

Surface Plasmon Polaritons (SPPs) have recently attracted great scientific interest because of their capability of controlling light in a sub-wavelength regime¹. Among various plasmonic devices, the metal-dielectric-metal (MDM) waveguide, which supports the propagation of SPPs in the metal-dielectric interface and manipulates light on a sub-wavelength scale, can be regarded as an ideal integrated photonic device^{2,3}. Due to the excellent features of easy fabrication and having deep sub-wavelength confinement of light with an acceptable propagation length for SPPs, MDM waveguide has been widely applied in Plasmon-induced transparency (PIT)^{4–6}, optical filter^{7–11}, switch^{12,13} and plasmonic sensor^{14–18}.

Based on the unique features of MDM waveguide, PIT can be observed in coupled optical resonator systems, which were theoretically predicted and experimentally demonstrated in recent researches^{19–27}. The stub resonator based on MDM waveguide has advantages of small size and simple fabrication technique. Chen *et al.* experimentally and numerically showed the plasmonic analogy of electromagnetically induced transparency (EIT) transmission in terahertz asymmetric waveguide with two stubs²⁰. Huang *et al.* demonstrated the EIT-like in periodic-stub-assisted plasmonic waveguides²⁸. Cao *et al.* used the Couple Mode Theory and the finite-difference time-domain (FDTD) to investigate the PIT in a bus waveguide coupled with two stub resonators^{23,24}. Chen *et al.* numerically predicted a multiple PIT can be obtained in a MDM waveguide side-coupled with a series of stub resonators²⁹. All of these are based on the single resonance mode in each stub resonator. Recently, Cao *et al.* used a single multimode stub resonator plasmonic system to realize double PIT³⁰. However, due to the complex interaction between the multiple modes, the study about multiple multimode stub resonators system is rarely reported.

In this paper, we propose a MDM waveguide coupled with two identical multimode stub resonators. A double PIT spectrum with higher transmission and quality factors (Q-factors) than those of single multimode stub resonator system can be observed. We extend the radiation oscillator theory (ROT)³¹ and propose a multimode coupled-ROT (MC-ROT) to investigate the spectral response theoretically for the first time. The analytical results accord well with the numerical results, which provide an effective theoretical analysis method for multiple multimode stubs coupled to MDM waveguide. In addition, the Q-factor is mainly influenced by the structural parameters can reach to 427. The Q-factors of the two PIT peaks have an opposite evolution tendency with the change of stubs parameters. The proposed structure is easy to fabricate and this work may pave the way for the realization of highly integrated and effective optical devices, such as the ultrasensitive sensors, efficient switches and narrow-band filters.

Figure 2. Magnetic field distributions of MDM waveguide side-coupled with single stub and two stubs for $L = 400$ nm and $d = 600$ nm at $\lambda = 664$ nm, 712 nm, 762 nm, 824 nm and 861 nm. (a–e) are the magnetic field distribution of structure with one stub; (f–j) are the magnetic field distribution of structure with two stubs.

Structure model and theoretical analysis

Figure 1(a) schematically shows MDM waveguide side-coupled with two identical stub resonators. The dielectric and metal in the structure are air and silver, respectively. The main structure parameters are the width ($w = 100$ nm) of bus waveguide, length (d) and width (L) of the stub resonator, and the distance between the two stubs is p ($p = 100$ nm). A Gaussian light pulse with wide wavelength profile (from 600 nm to 1200 nm, Bandwidth = 250 nm) and normalized amplitude (Amplitude = 1) is incident along x -axis, SPP wave can be formed on metal-dielectric interface and confined in the waveguide. The width (L) of the stub resonators is large enough that the resonators can provide multiple modes.

When $d = 600$ nm, $L = 400$ nm, transmission spectra of a single and two multimode stubs coupled to bus waveguide are depicted in Fig. 1(b), respectively. The blue curve represents double PIT peaks can be observed in single multimode stub resonator system. The transmission is greatly enhanced and the PIT peaks become very sharp with narrow bandwidth when the bus waveguide coupled with two multimode stub resonators. The transmission of the left peak increases from 28% to 82%, and the full width at half maximum (FWHM) decreases from 50 nm to 10 nm. The transmission of the right peak increases from 18% to 80%, and the FWHM decreases from 63 nm to 13 nm. The Q-factor is defined as $Q = \lambda/\Delta\lambda$ (here λ is the wavelength of the peak and $\Delta\lambda$ is the FWHM of the PIT windows), which increases from 14 to 71 and 13 to 63 for the left peak and right peak, respectively.

In order to realize the physical mechanism of the changes in Fig. 1(b), we display the field distributions of the MDM waveguide coupled with a single stub and two stubs at $\lambda = 664$ nm, 712 nm, 762 nm, 824 nm, 861 nm in Fig. 2(a–j), respectively. Among these wavelengths, $\lambda = 664$ nm, 762 nm, 861 nm are the resonance wavelengths and $\lambda = 712$ nm, 824 nm are the PIT peaks wavelengths of stub with $d = 600$ nm, $L = 400$ nm. The resonance modes can be denoted as TM_{mn} , where m and n denote the number of node of standing waves in horizontal and vertical directions in the stub resonator, respectively. There are three resonance modes simultaneously existing in each stub resonator, which can be expressed as TM_{11} ($\lambda = 664$ nm), TM_{01} ($\lambda = 762$ nm), and TM_{10} ($\lambda = 861$ nm),

respectively. The two stub resonators and the connected waveguide act as a Fabry-Perot (FP) interferometer. The incident light can be reflected back and forward by each stub resonator. At the resonance wavelengths, the field distributions and intensity in the two stub systems are uniform with those in the single stub system. Most of the power is confined in the first stub or reflected back, with almost no power transport out, as illustrated in Fig. 2(a,c,e,f,h,j). At the PIT peaks wavelengths, a good part of the propagating radiation can exit the waveguide, and the rest can be reflected by the two stubs. There is a destructive interference between the two reflected waves in the waveguide, which reduces the reflected power and enhances the transmission, as depicted in Fig. 2(g,i). Moreover, the bandwidth of the transmission spectrum is inversely proportional to the effective length of the FP interferometer³². The effective length of the FP interferometer in two stub resonators system is larger than that in a single stub system, therefore, the PIT spectrum with narrow bandwidth can be observed in our proposed structure, as shown in Fig. 1(b).

According to ROT³¹, a single resonance mode motivated directly or indirectly by the input exists in each resonator. In our structure, there are three resonance modes directly motivated by the input in each stub resonator, simultaneously. Considering the mutual coupling among the three modes, we propose a MC-ROT to investigate the spectral response of the multimode system for the first time. The simple model with three coupled harmonic oscillators can be described as

$$\omega_1^{-2}\ddot{a}_1(t) + \gamma_1\omega_1^{-1}\dot{a}_1(t) + a_1(t) = f(t) - \kappa_{12}a_2(t) - \kappa_{13}a_3(t) \quad (1)$$

$$\omega_2^{-2}\ddot{a}_2(t) + \gamma_2\omega_2^{-1}\dot{a}_2(t) + a_2(t) = f(t) - \kappa_{12}a_1(t) - \kappa_{23}a_3(t) \quad (2)$$

$$\omega_3^{-2}\ddot{a}_3(t) + \gamma_3\omega_3^{-1}\dot{a}_3(t) + a_3(t) = f(t) - \kappa_{13}a_1(t) - \kappa_{23}a_2(t) \quad (3)$$

the three radiative oscillators with resonance frequency ω_i ($i = 1, 2, 3$) and damping factor γ_i ($i = 1, 2, 3$) are described by the excitation $a_i(t)$ ($i = 1, 2, 3$) and the external force $f(t)$. Every two oscillators are linearly coupled with coupling strength κ_{if} ($i \neq f$). For simplicity, we set the coupling strength $\kappa_{12} = \kappa_{23} = \kappa_{13} = \kappa$, approximately.

Equations (1)–(3) can be solved in the frequency domain by assuming a solution of the form $a_i(t) = a_i(\omega) \cdot \exp(-i\omega t)$ and $f(t) = f(\omega) \cdot \exp(-i\omega t)$, the electric current sheet with surface conductivity $\sigma_{se} = -i\omega [a_1(\omega) + a_2(\omega) + a_3(\omega)]/f(\omega)$ is introduced to describe this effective response, which can be written as

$$\sigma_{se} \approx \frac{-i\omega[(D_2 - \kappa)(D_3 - \kappa) + (D_1 - \kappa)(D_3 - \kappa) + (D_1 - \kappa)(D_2 - \kappa)]}{D_1D_2D_3 - \kappa^2(D_1 + D_2 + D_3) + 2\kappa^3} \quad (4)$$

where $D_i = 1 - (\omega/\omega_i)^2 - i\gamma_i(\omega/\omega_i)$. So the transmission can be calculated in the following form³¹

$$T = \left| \frac{2}{2 + \xi\sigma_{se}} \right|^2 \quad (5)$$

where $\xi = \beta(L)L/\omega\varepsilon_0\varepsilon_i^{33}$ is the wave impedance, ε_0 is the permittivity of vacuum, ε_i is the relative permittivity of the filled medium in resonators and $\beta(L)$ is the propagation constant in MDM resonators. Using the transfer matrix method (TMM)³³ and expanding the oscillator model to the second stub, the transmission of the two stubs coupled structure can be expressed as

$$T_2 = \left| \frac{A_{+4}}{A_{+1}} \right|^2 = \left| \frac{4}{\xi_2\sigma_2 + (\xi_1\sigma_1 + 2)(\xi_2\sigma_2 + 2)} \right|^2 \cdot \exp(-2iKp) \quad (6)$$

where $K = \alpha + i\beta$ is the Bloch wave vector. Using the theoretical analysis mentioned above, we can analyze the transmission spectra in the multiple multimode resonator systems.

Simulation results and discussions

We further investigate the spectral response of the proposed plasmonic waveguide system with different structural parameters. Figure 3 shows the transmission characteristics for the system with two identical stubs under different width L . Here, the other structural parameters are the same as those in Fig. 1(a).

As shown in Fig. 3(a,c), the transmission characteristics of the two peaks show different evolution trend as L increases. The left peak has a high transmission and broad bandwidth while the right peak possesses a low transmission and narrow bandwidth when $L = 380$ nm. As L increases, the transmission and the FWHM decrease for the left peak and increase for the right peak. The FDTD simulations are in excellent agreement with the theoretical fittings. Particularly, the right peak almost disappears when $L = 370$ nm and the left peak vanishes when $L = 430$ nm. This phenomenon can be attributed to the resonance wavelengths shift as L increases. As Fig. 3(b) shows, the resonance wavelengths of TM_{11} and TM_{10} have a red-shift while TM_{01} has a blue-shift with the increasing of L . The left and right peaks originate from the destructive interference between TM_{01} and TM_{11} , TM_{01} and TM_{10} , respectively. The resonance wavelengths of TM_{01} and TM_{10} overlap and there is about 150 nm wavelength detuning between TM_{11} and TM_{01} when $L = 370$ nm. Hence, the right peak almost disappears while the left peak has a high transmission and broad bandwidth in the transmission spectrum. With the increase of L , the wavelength detuning between TM_{01} and TM_{10} enlarges, resulting in an increase for the transmission and FWHM of the right peak. However, the wavelength detuning between TM_{11} and TM_{01} has an opposite trend, the transmission and FWHM of the left peak decrease as L increases.

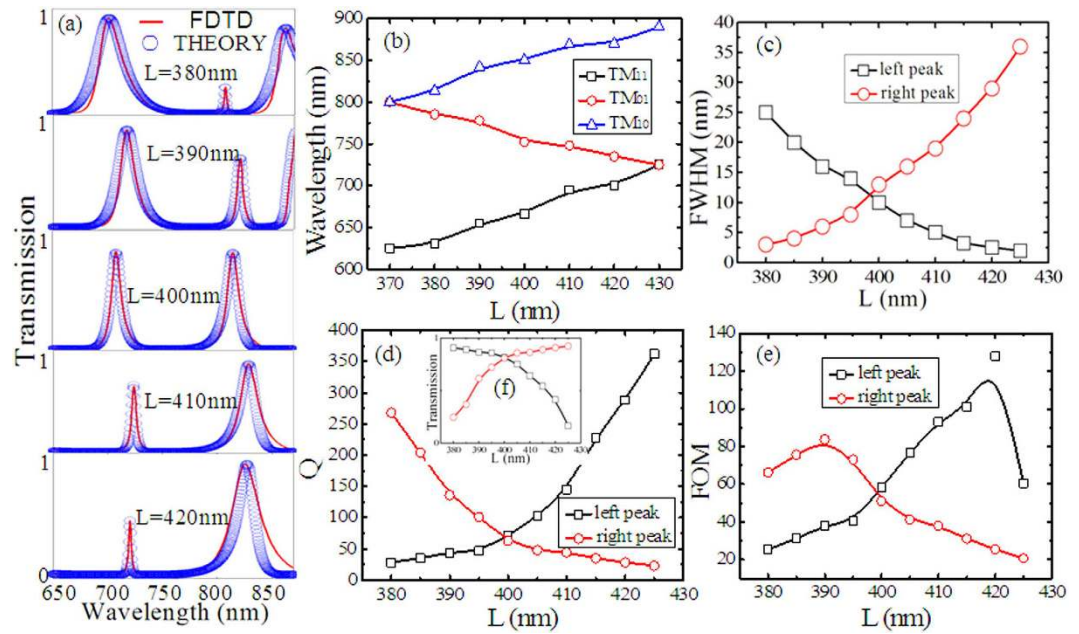

Figure 3. (a) Transmission spectra versus different L . The red solid curves are the simulation results and the blue circles are theoretical fittings. The other geometrical parameters are $w = 100$ nm, $d = 600$ nm, $p = 100$ nm. (b) The resonant wavelengths ($\lambda_1, \lambda_2, \lambda_3$) of TM_{11} , TM_{01} and TM_{10} modes versus L . (c–f) The FWHM, Q-factors, FOM and transmission corresponding to the two transparent peaks for different L , respectively. The black curve with squares represents the values of the left peak and the red curve with circles represents the values of the right peak. The fitting parameters are set as $\kappa = 0.01$; ($L = 380$ nm) $[\lambda_1, \lambda_2, \lambda_3] = [630, 785, 813]$ nm, $[\gamma_1, \gamma_2, \gamma_3] = [0.002, 0.001, 0.0013]$; ($L = 390$ nm) $[\lambda_1, \lambda_2, \lambda_3] = [655, 778, 842]$ nm, $[\gamma_1, \gamma_2, \gamma_3] = [0.002, 0.001, 0.002]$; ($L = 400$ nm) $[\lambda_1, \lambda_2, \lambda_3] = [666, 752, 850]$ nm, $[\gamma_1, \gamma_2, \gamma_3] = [0.0015, 0.001, 0.0015]$; ($L = 410$ nm) $[\lambda_1, \lambda_2, \lambda_3] = [695, 748, 869]$ nm, $[\gamma_1, \gamma_2, \gamma_3] = [0.001, 0.001, 0.0012]$; ($L = 420$ nm) $[\lambda_1, \lambda_2, \lambda_3] = [700, 735, 870]$ nm, $[\gamma_1, \gamma_2, \gamma_3] = [0.0008, 0.001, 0.0008]$.

The Q-factors of PIT peaks are also investigated and depicted in Fig. 3(d). It is seen that the changes of L also have different effects on the Q-factors of the two peaks. The Q-factor of the left peak increases from 28 to 362 as L ranges from 380 nm to 425 nm, while the Q-factor of the right peak decreases from 268 to 23. The inset Fig. 3(f) is the transmission of the two peaks as a function of L . When the Q-factor increases (decreases), the transmission gets weakened (enhanced), a tradeoff between Q-factor and transmission can be observed. In order to quantize the tradeoff, the product of Q-factor and transmission (T) is defined as the figure of merit ($FOM = Q \cdot T$). The FOM of the two peaks with different L is plotted in Fig. 3(e), the maximum FOM = 128 for the left peak with a Q-factor of 288 and transmission of 44% when $L = 420$ nm, and the maximum FOM = 84 for the right peak with a Q-factor of 136 and transmission of 62% when $L = 390$ nm.

At last, we investigate the impact of the stub resonators length d on transmission characteristics in this plasmonic waveguide system. As shown in Fig. 4(a,c), the transmission and bandwidth increase for the left peak and decrease for the right peak as d increases. This evolution trend is opposite to those in Fig. 3. The FDTD simulation results are well consistent with the theoretical ones. The wavelengths of the three resonance modes versus d are plotted in Fig. 4(b). For various d , the resonance wavelengths of TM_{11} and TM_{10} are nearly constant. However, there is a liner relationship for the TM_{01} mode. The resonance wavelengths of TM_{01} and TM_{11} nearly overlap and the wavelength detuning of 200 nm is found between TM_{01} and TM_{10} when $d = 530$ nm. Therefore, the left peak almost disappears and the right peak has a high transmission and broad bandwidth in the spectrum. With the increase of d , the wavelength detuning between TM_{01} and TM_{11} enlarges, the transmission and FWHM of the left peak increase. However, the wavelength detuning between TM_{10} and TM_{01} has an opposite trend, the transmission and FWHM of the right peak decrease as d increases.

The Q-factors of the two peaks versus d are displayed in Fig. 4(d). The Q-factor of the left peak decreases from 339 to 25 as d increases, while the Q-factor of the right peak increases from 18 to 427. The inset Fig. 4(f) is the transmission of the two peaks as a function of d . It is worth noting that there is also a tradeoff between Q-factors and transmission. The FOM of the two peaks with different d is plotted in Fig. 4(e). The maximum FOM = 114 for the left peak with a Q-factor of 230 and transmission of 49% when $d = 570$ nm, and the maximum FOM = 94 for the right peak with a Q-factor of 168 and transmission of 56% when $d = 630$ nm. These results, obtained by fully considering the tradeoff, can provide some guidance for the design of efficient photonic devices.

Conclusions

In summary, we have numerically and analytically demonstrated the PIT effect with high Q-factor in a MDM waveguide side-coupled with two multimode stub resonators. The Q-factors of PIT peaks in two stub resonators system are larger than those in the single stub resonator system. The coherence between the theoretical and

(c–f) The FWHM, Q-factors, FOM and transmission corresponding to the two transparent peaks for different d , respectively. The black curve with squares represents the values of the left peak and the red curve with circles represents the values of the right peak. The fitting parameters are set as $\kappa = 0.01$; ($d = 560$ nm) [$\lambda_1, \lambda_2, \lambda_3$] = [668, 702, 835] nm, [$\gamma_1, \gamma_2, \gamma_3$] = [0.0045, 0.001, 0.0004]; ($d = 580$ nm) [$\lambda_1, \lambda_2, \lambda_3$] = [666, 730, 845] nm, [$\gamma_1, \gamma_2, \gamma_3$] = [0.003, 0.001, 0.0004]; ($d = 600$ nm) [$\lambda_1, \lambda_2, \lambda_3$] = [666, 752, 850] nm, [$\gamma_1, \gamma_2, \gamma_3$] = [0.0015, 0.001, 0.0015]; ($d = 620$ nm) [$\lambda_1, \lambda_2, \lambda_3$] = [661, 790, 850] nm, [$\gamma_1, \gamma_2, \gamma_3$] = [0.0015, 0.001, 0.0015]; ($d = 640$ nm) [$\lambda_1, \lambda_2, \lambda_3$] = [662, 820, 851] nm, [$\gamma_1, \gamma_2, \gamma_3$] = [0.001, 0.001, 0.003].

numerical results validates the availability of the derived MC-ROT in effectively and conveniently describing the multimode system. By manipulating the parameters of the two stub resonators, a tunable Q-factor with a maximum of 427 can be obtained. In particular, the Q-factors of the two PIT peaks have an opposite evolution tendency with the change of the stubs parameters. With regard to the tradeoff between the Q-factor and the transmission, engineering the resonator geometry can lead to a maximum FOM of 128. Owing to the simple configuration and compactness, the high Q-factor structure has great potential applications in ultrasensitive sensors, optical switches and optical filters in integrated optical circuits.

Methods

The frequency dependent optical property of the silver nanostructure is approximated by the Drude model: $\varepsilon(\omega) = \varepsilon_\infty - \omega_p^2 / (\omega^2 + i\omega\gamma_p)$, with $\omega_p = 1.38 \times 10^{16} \text{ s}^{-1}$ is the bulk plasmon frequency, $\varepsilon_\infty = 3.7$ and $\gamma_p = 2.73 \times 10^{13} \text{ s}^{-1}$ represents the damping rate. These values are obtained by fitting the experimental results report in³⁴. With these parameters, the permittivity of silver in Drude model agrees well with the experimental result in the visible and a part of near-infrared waveband, Drude model can be used to effectively simulate the optical properties of our structure in this waveband. The characteristic spectral responses of the structure are performed by the two-dimensional FDTD simulation. The spatial and temporal steps are set as $\Delta x = \Delta y = 5$ nm, and $\Delta t = \Delta x / 2c$ (c is the velocity of light in vacuum), respectively. We perform the FDTD simulations with a perfect matched layer (PML) boundary condition.
