## Abstract

Two Korean endemic pheretimoid *Amyntas* Kinberg, 1867 species belonging in family Megascolecidae s. stricto are sketched, dissected and described. *Amyntas daeari* Blakemore **sp. n.** has spermathecae in 6/7/8 complying with an *A. tokioensis* spp.-group, whilst *Amyntas jinburi* Blakemore **sp. n.** has spermathecal pores in 5 & 6 strictly complying with Sims & Easton's (1972) *A. canaliculatus*-group. A definitive COI gene barcode is provided for the holotype of *A. daeari* but the age since collection or preservation of the *A. jinburi* type in 2000 precluded its mtDNA extraction at this time.

## Keywords

Soil fauna, invertebrate biodiversity, new endemic taxa, molecular barcodes

## Introduction

Specimens from the collection of NIBR contribute to ongoing earthworm surveys as part of understudied non-insect invertebrates of the Korean Peninsula (Blakemore 2012a, b, 2013a, b, Blakemore et al. 2012a, b). Two specimens are described below belonging to a pheretimoid (*Pheretima* auct.) group of Oriental origin that provides approximately 970 valid species from 1,200 nominal taxa (Blakemore 2008a). *Amyntas* Kinberg, 1867 is the most diverse of the pheretimoid genera with some species common to Korea and Japan where faunal totals both approach 100 megadrile earthworm taxa (Blakemore 2003, 2008b, c, 2012c, d). The probable endemics are here added to the Korean list.

## Materials and methods

Taxonomic determinations follow the methodology and classifications in Sims and Easton (1972) and Blakemore (2010). Abbreviations are: C – circumference, GMs – genital markings, lhs – left hand side and rhs – right hand side.

Specimens, now in 80% Ethanol, are lodged in the NIBR facility. Small tissue samples taken for mtDNA COI barcoding as proposed 10 yrs ago by Hebert et al. (2003) used similar methods as per Blakemore et al. (2010) with preliminary analysis via BLAST programs ([www.blast.ncbi.nlm.nih.gov/BLAST.cgi](http://www.blast.ncbi.nlm.nih.gov/BLAST.cgi)).

Discussion is confined to remarks after each species' description. For brevity, not all taxonomic authorities are cited in References as these may be sought elsewhere.

urn:lsid:zoobank.org:act:E6B103F4-2FFE-4A05-BCD8-356A90754AC5

[http://species-id.net/wiki/Amyntas\\_daeari](http://species-id.net/wiki/Amyntas_daeari)

**Material examined.** IV0000261261, mature specimen complete but broken in two at clitellum after being figured and dissected. Collected from small valley at Jeollabuk-do, Wanju-gun, Dongsang-myeon, Daea-ri (35.9801N, 127.2981E); collected 27<sup>th</sup> July, 2012 by Dr Hong-Yul Seo. DNA tissue sample code – w53.

**Etymology.** Noun from location.

**Figure 1.** *Amynthus daeeri* sp. n. showing ventral view with spermathecae, their composite genital marking glands and 18lths prostate *in situ* plus incised intestinal caecum in 27; dorsal view of prostomium; [boxed are lateral views of spermathecal pores and male field in 18rths to same scale].

**Diagnosis.** *Amynthas* with two pairs of spermathecal pores in 6/7/8 complying with an *A. tokioensis* -group; spermathecae with compressed clavate diverticula; GMs median to spermathecal and male pores with patches around the former and the latter bracketed laterally by small C-shaped clefts.

**Distribution.** Only known from a single specimen from type locality.

**Habitat.** In litter layer in forest.

**Behaviour.** Habitat, pigmentation and gut contents indicate activity in the litter layer.

**Description. Length.** 150 mm.

**Width.** ca. 7 mm at male pore level.

**Segments.** 107.

**Colour.** Brown in alcohol, possibly darker in life as liquid was stained.

**Prostomium.** Open epilobous.

**First dorsal pore.** 12/13.

**Setae.** Ca. 60 per segment, approximately 22-24 between spermathecal and male pores.

**Nephropores.** Not found.

**Clitellum.** Annular 14-16, setae occluded.

**Male pores.** On 18 centred on small, round porophore (found by following a pin from prostate gland exit) with GMs antero-median and shallow clefts laterally (that function as seminal ducts and/or suction cups?).

**Female pores.** Single on 14.

**Spermathecal pores.** 6/7/8 ca 0.3 C apart at edge of puckered area and lateral to GMs.

**Genital markings.** Paired discs just median to male and spermathecal pores as noted; composite glands on spermathecal pore GMs but none found for GMs near male pores although the body here is macerated and they may well have broken off and dissipated.

**Septa.** Nephridial forests on septa 5 & 6; 7/8 thin, 8/9/10 aborted.

**Dorsal blood vessel (dbv).** Single.

**Hearts.** Last hearts in 13 (preceding vascularization unclear/damaged).

**Gizzard.** Single in 8-9.

**Calciferous glands.** Absent.

**Intestine.** Indeterminate as specimen macerated; caeca ventrally incised from 27; typhlosole not noted.

**Nephridia.** Meroic.

**Male organs.** Holandric, seminal vesicles in 11 & 12.

**Ovaries.** In 13 as usual.

**Prostates.** Racemose glands in 17-19, duct short and muscular.

**Spermathecae.** Two pairs in 7 and 8; that in 7lhs inflated, that in 8lhs deflated (showing how meaningless such a distinction is although relied on by some authors).

**Gut contents.** Coarse organic debris, i.e., a litter diet suggesting superficial feeding.

**DNA COI barcode.** >w53 *A. daeari* Holotype.

megaBLAST result: “*Amyntas tappensis*” (AB542547.1) from Japan max. identity <88% this then is a different and likely new taxon. The closest match from current Korean studies with BLASTn identity 565/653 (87%) is WO49, an immature *Amyntas* sp. from Jeju that itself comes closest to the *A. tokioensis*/*M. hilgendorfi* spp. complexes (see Blakemore, 2013a: Appendix).

**Remarks.** Of *Amyntas* species with spermathecae in 6/7/8, twenty or so in the *Amyntas tokioensis*-group of Sims and Easton (1972) mostly have manicate caeca, such as *A. kanrazanus* (Kobayashi, 1937); about twenty other species, many placed in this group after 1972, have simple intestinal caeca. Only four have simple incised caeca as here, but they all differ in characteristics of their GMs, at least, and none of these latter are known from Korea (Blakemore unpublished). The incised caeca is assumed to be a characteristic transitional or intermediate from simple to complex/manicate. The GMs in 7-8 obviously correspond to those in 18 during amphimixis but it is not known whether they interlock serially. The shape of the spermathecae and spermathecal pores are further distinguishing characteristics of *A. daeeri* that, along with its objective DNA barcode data, now serve to define this taxon.

***Amyntas jinburi* sp. n.**

urn:lsid:zoobank.org:act:9BA5299B-0BA0-4E50-8EAC-C76C2D66B2EA

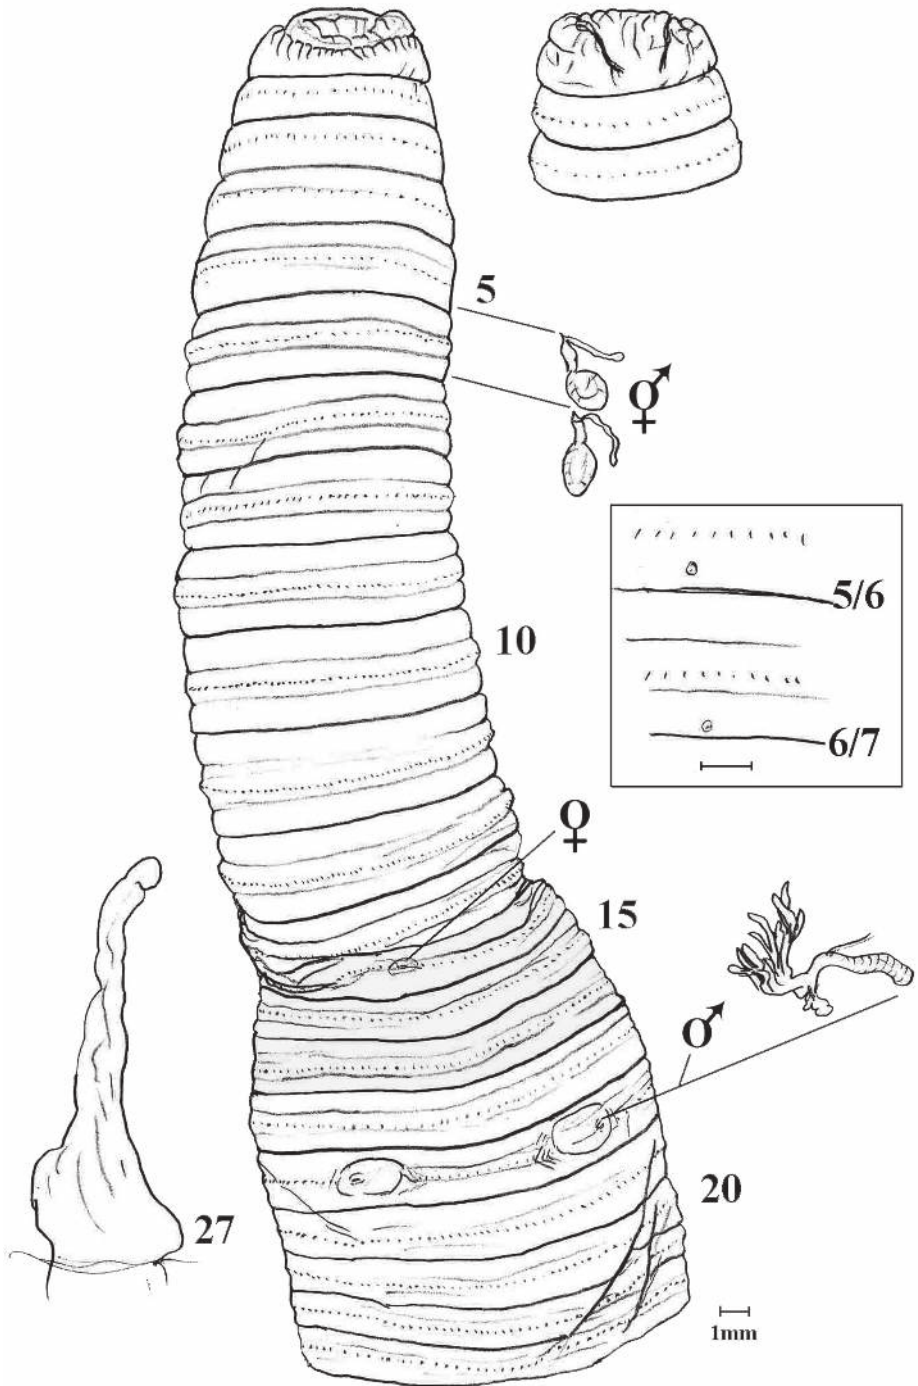

[http://species-id.net/wiki/Amyntas\\_jinburi](http://species-id.net/wiki/Amyntas_jinburi)

**Material examined.** IV0000213690, sub-mature specimen, figured and dissected. From Gangwon-do, Goseong-gun, Ganseong-eup, Jinbu-ri (ca. 38.2961N, 128.3546E) just north of Seoraksan Park on East coast; collected 1<sup>st</sup> – 2<sup>nd</sup> June, 2000 by unknown person(s) and deposited in NIBR. DNA tissue sample w61b (unsuccessful at this time).

**Etymology.** Noun from location.

**Diagnosis.** *Amyntas* with two pairs of spermathecal pores in 5 & 6; long, clavate spermathecal diverticula; simple caeca; and GMs absent except for large patches surrounding male pores.

**Distribution.** Known only from single specimen from type locality.

**Figure 2.** *Amynthus jinburi* sp. n. showing ventral view with spermathecae and 18rhs prostate *in situ* plus simple intestinal caecum in 27; dorsal view of prostomium; [boxed is 2X lateral view of spermathecal pores in 5 & 6rhs].

**Habitat.** Jinburi is a remote, mountainous and forested area

**Behaviour.** Possibly deep burrowing and geophageous (from gut contents).

**Description. Length.** 210 mm.

**Width.** ca. 10 mm at male pore level.

**Segments.** 143 with some secondary annulation (from preservation?).

**Colour.** Bleached pale yellow in aged alcohol, possibly darker in life.

**Prostomium.** Open epilobous.

**First dorsal pore.** 11/12.

**Setae.** >100 per segment; e.g. 100+ on 11 and 112 counted on segment 12; approximately 16 setae intervene between male pore pads that are asexual on 18.

**Nephropores.** Not found.

**Clitellum.** Slightly darker at 14-16.

**Male pores:** On 18 on small, rounded and flat porophores.

**Female pores.** Single on 14.

**Spermathecal pores.** At posterior of 5 and 6 approximately 0.3 C apart.

**Genital markings.** None (sub-adult?).

**Septa.** Nephridial forests on septa 5 & 6; 5/6/7/8 thick, 8/9 thin to base of gizzard, 9/10 aborted.

**Hearts.** Seen in 11-13 (aborted in 10?).

**Gizzard.** Single in 8-9.

**Calciferous glands.** Absent.

**Intestine.** From 15; caeca simple elongate from 27; typhlosole not noted.

**Nephridia.** Meroic.

**Male organs.** Holandric, testes small in 10 & 11; seminal vesicles in 11 & 12.

**Ovaries.** Compact in 13; ovisacs not found in 14.

**Prostates:** Racemose glands not fully developed in 18 on short, muscular duct.

**Spermathecae.** Two pairs in 6 & 7 exiting to anterior of 5/6 and 6/7 in 5 & 6 (Fig. 2).

**Gut contents.** Filled with yellow soil, i.e. probably a deep-burrowing subsoil geophage.

**DNA COI barcode.** >w61b – nil result, DNA not extractable on this older material that may have been fixed in formalin (although there was no odour) or denatured by pH.

**Remarks.** Of all 970 pheretimoid species (Blakemore 2008a), only two are known to have spermathecal pores in 5 & 6: viz. *Amyntas serenus* (Gates, 1936) from Pahang, Malaysia that also lacks GMs, and *A. breviclitellatus* (Do & Tran, 1995) from Vietnam that differs, at least, in its GMs in 7, 18 and 19. From “Kôryô” Korea (about 30 Km from Seoul), *Amyntas fibulus fibulus* (Kobayashi, 1936: 159) is superficially similar but has spermathecal pores anteriorly in 6 & 7 (rather than posteriorly in 5 & 6) plus its caeca are incised ventrally (rather than smooth); ditto for *A. fibulus ranunculus* (Kobayashi, 1936: 162) that further has slits lateral to male pores. Interestingly, Kobayashi’s (1936: fig. 6) sketch of a prostate gland of *A. fibulus* closely resembles the current specimen’s gland (Fig. 2).

It should be here noted that Sims and Easton (1972) inadvertently place these two *fibulus* taxa in an *Amyntas morrisoni*-group defined with spermathecae in 5/6/7 despite Kobayashi (1936: 159) stating “*Spermathecal pores, minute, 2 pairs anteriorly located on*

VI and VII, closely to the intersegmental furrows”, i.e. strictly complying with Sims & Easton’s *canaliculatus*-group (then comprised of *benignus* Chen, 1946; *canaliculata* Gates, 1932; *ralla* Gates, 1936: 104; and *rallida* Gates, 1936: 106). It appears that many of Hong and James’ (2001: 67, 68, 69, 75) taxa have a similar attribute although their descriptions are ambiguously stated, such as: “*Spermathecal pores in 5/6 and 6/7...at or near leading edge of vi, vii*” and no useful figures are provided for the reader to decide.

If spermathecal pores were in 5/6/7 in any of the above taxa, then the *morrisi*-group’s possible nearest relatives from Korea would likely be *A. koreanus* (Kobayashi, 1938: 115) that, however, has manicate caeca; or *A. kobayashii* (Kobayashi, 1938: 119) and *A. geojeinsulae* (Song & Paik, 1970) that both have male fields from 17–19 but differ in simple or incised caeca, respectively; or *A. assimilis* Hong & Kim, 2002 that, like many of its similar cited taxa, has seminal grooves on 18.

The current species has simple, superficial male pores on large disc-like pads on 18. Although not fully mature, it appears unique in the Korea fauna on its combination of this aspect of its male field, spermathecal pores in 5 & 6 and its profusion of setae that number more than 100 per segment, combined with simple elongate intestinal caeca.

Fresh topotypic material is required to confirm these conclusions and to provide definitive DNA data, unless refinement of techniques allows extraction from older types.

## Acknowledgements

This work was supported by a grant from the National Institute of Biological Resources (NIBR), funded by the Ministry of Environment (MOE) of the Republic of Korea. Dr Hong-Yul Seo of NIBR provided one of the samples, Seunghan Lee performed DNA analysis and Prof. Wonchoel Lee facilitated the study at Hanyang University, Seoul. All taxonomic work and decisions are the responsibility of the primary author. Thanks to ZooKeys editor and anonymous referees for constructive comments to improve the MS.
