**Worldwide prevalence of sexual harassment toward nurses: a comprehensive meta-analysis of
observational studies**

Running head: Sexual harassment against nurses

Author Manuscript

Abstract

Aims: Sexual harassment toward nurses is a major concern universally, but no meta-analysis on the worldwide prevalence of sexual harassment toward nurses has yet been published. This study examined the worldwide prevalence of sexual harassment against nurses and explored its moderating factors.

Design: Meta-analysis of observational studies.

Data sources: The PubMed, PsycINFO, EMBASE and Web of Science databases from their commencement date to February 2018 were systematically and independently searched by two investigators.

Review Methods: Data on the prevalence of sexual harassment experienced by nurses were extracted and pooled using the random-effects models.

Results: A total of 43 studies covering 52,345 nurses were included in the analyses. Female nurses accounted for 83.87% of the 32,970 subjects in 25 studies with available data on gender ratio. The prevalence of sexual harassment toward nurses in the past 12 months and during nursing career were 12.6% (95% CI: 10.9%–14.4%) and 53.4% (95% CI: 23.1%–83.7%), respectively. Gender, use of the WHO questionnaires, lower middle income and high-income countries, sample size, survey year and mean age of subjects were significantly associated with the prevalence of sexual harassment.

Conclusion: The high prevalence of sexual harassment against nurses found in this meta-analysis represents the ongoing sexism and deleterious effects (e.g., poor work quality and efficiency, increased stress and job dissatisfaction) in the profession. Appropriate preventive measures, training and empowerment of nurses are needed to ensure workplace safety and equality in this profession.

Impact:

- The study addressed the worldwide prevalence of sexual harassment against nurses and its moderating factors.
- The prevalence of sexual harassment in the past 12 months and during nursing career were 12.6% and 53.4%, respectively.
- Health authorities and hospital administrators should develop organizational policy and preventive strategies to ensure nurses' workplace safety and equality.

Key words: female, meta-analysis, nurse, sexual harassment

Registration number: CRD42018089653

INTRODUCTION

Sexual harassment refers to unwanted, unreciprocated and unwelcome behaviour of a sexual nature that is offensive to the persons involved and could make the persons feel threatened, humiliated or embarrassed (WHO, 2002). In recent decades, sexual harassment toward health professionals, particularly female nurses, has increasingly been a focus of attention worldwide (Clark, Zuccala, & Horton, 2017; Nelson, 2014; Valente & Bullough, 2004). Women account for over 70% of the health and social workforce globally especially in the nursing profession (WHO, 2018). Some studies reported that compared with male nurses, female nurses are more likely to be sexually harassed in workplaces by people who they care for and their family or relatives and even their co-workers (Boafo, Hancock, & Gringart, 2016; Celik & Celik, 2007; Magnavita & Heponiemi, 2011). Such gender disadvantage is often tolerated as a necessary "evil" or a cost of

keeping a job and not reported in many cases (Celik & Celik, 2007; Fitzgerald, 1993; Valente & Bullough, 2004).

BACKGROUND

In the past decades some studies on sexual harassment have been conducted, but the prevalence of sexual harassment in nurses varied greatly worldwide, ranging from 0.7% to 76% (Abou-ElWafa, El-Gilany, Abd-El-Raouf, Abd-Elmouty, & El-Sayed, 2015; Grieco, 1987; Kamchuchat, Chongsuvivatwong, Oncheunjit, Yip, & Sangthong, 2008). This is partly attributed to the discrepancies in assessment tools, sample size, sampling methods and relevant policies and legislation. Sexual harassment toward nurses has deleterious effects, such as increased stress, poor mental health and quality of life, burnout, job dissatisfaction, poor work quality and efficiency (Ali, Saied, Elsabagh, & Zayed, 2015; Charney & Russell, 1994; Kisa, Dziegielewski, & Ates, 2002; Mushtaq, Sultana, & Imtiaz, 2015; Nielsen et al., 2017).

To develop effective preventive measures and policies to lower the risk of sexual harassment in the nursing profession, ensure the allocation of health human resources, it is necessary to understand the epidemiology of sexual harassment affecting the nursing profession.

THE REVIEW

Aims

We conducted a comprehensive meta-analysis to explore the worldwide prevalence of sexual harassment toward nurses and examine its associated moderating factors.

Design

In the literature search, the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) (Moher, Liberati, Tetzlaff, Altman, & Group., 2009) and the Meta-analysis of Observational Studies in Epidemiology (MOOSE) guidelines (Stroup et al., 2000) were followed. The protocol was registered in the International Prospective Register of Systematic Reviews (PROSPERO) with the registration number of CRD42018089653.

Search methods and outcomes

Two investigators (LL and DM) independently identified potential publications in PubMed, PsycINFO, EMBASE and Web of Science from their commencement date to February 6, 2018. The following search words were used: (nurses OR nurs* OR (nursing staff) OR (nursing personnel) OR (registered nurses)) AND (sexual harassment) AND (survey OR investigation OR (cross-sectional) OR rate OR prevalence OR epidemiology OR proportion OR percentage OR ratio). Reference lists of the selected literatures were also searched manually to ascertain relevant additional studies.

Search outcomes

Studies were included if they met the following criteria: a) cross-sectional or cohort studies (only the baseline data were extracted for analyses); b) having data on prevalence of sexual harassment or relevant information in nurses (i.e., nurses, nursing assistant and midwife) that could generate the prevalence of sexual harassment defined by the respective studies. To date there has been no agreement on the definition of sexual harassment. Studies that only reported relevant behaviours, such as sexual violence or sexual abuse toward nurses, but did not define “sexual harassment”, were excluded. Two investigators (LL and DM) independently screened the initial search literatures by reviewing titles and abstracts and later read full texts to identify eligible studies. If there were more than one publication based on an identical database, only the one with the largest
This article is protected by copyright. All rights reserved

sample size was included for analysis.

Quality appraisal

The 22-item Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) was used to assess the quality of included studies (von Elm et al., 2007). In this meta-analysis studies with a STROBE total score >11 were considered as “high quality” (Cao et al., 2015).

Data abstraction

The investigators (LL and DM) extracted the data independently. Any discrepancies in the process were resolved by a discussion with a third researcher (XYT). The following study characteristics were extracted and tabulated: country/region, response rate, sampling method, sample size, mean age, the proportion of female nurses, assessment tools, year of survey, prevalence timeframe and the prevalence of sexual harassment.

Synthesis

The data analyses were conducted using the Comprehensive Meta-Analysis software version 2 (Biostat Inc., Englewood, New Jersey, USA) and STATA version 12.0 (Stata Corporation, College Station, Texas, USA). The square root transformation method (Freeman & Tukey, 1950) was used to synthesize the prevalence of sexual harassment with 95% confidence intervals (CI). Heterogeneity across studies was measured by I^2 statistic; high heterogeneity was defined as $I^2 > 50\%$ (J. P. Higgins, Thompson, Deeks, & Altman, 2003). The random-effects model was used if the I^2 was larger than 50%; otherwise, the fixed-effects model was applied (J. P. Higgins et al., 2003).

To detect the possible sources of heterogeneity, subgroup analyses and meta-regression analyses were performed (meta-regression analysis was only conducted when 10 or more studies

with relevant data were available (Julian PT Higgins & Green, 2011). Subgroup analyses of the 12-month prevalence of sexual harassment were conducted based on the following categorical variables: economic level classified by the World Bank (low income/lower middle income/upper middle income and high income) (Worldbank, 2017); assessment tools (measure on workplace violence-World Health Organization (WPV-WHO; i.e., measures recommended by the WHO and the programs launched by the International Labour Office (ILO), International Council of Nurses (ICN) and WHO and Public Services International (PSI) (WHO, 2003) / self-designed questionnaires / other measures). Sample size was dichotomized by the median splitting method to conduct subgroup analyses. Due to inadequate data available, subgroup analyses of sexual harassment in nursing career was not performed. Meta-regressions were conducted based on the following continuous variables: proportion of female nurses, mean age, year of survey and sample size. Funnel plots and Egger's regression model (Egger, Davey Smith, Schneider, & Minder, 1997) were used to check publication bias. Sensitivity analyses were performed by removing the included study individually to assess the consistency of the results. The level of significance was set at $p < 0.05$ (two-tailed).

Results

Search results

Out of 518 potential papers identified, a total of 43 studies with 52,345 nurses met the inclusion criteria and were included for analyses (Figure 1). The two studies that reported prevalence of two types of (internal and external) verbal sexual harassment separately (Demir & Rodwell, 2012; Rodwell & Demir, 2014) and three studies that reported physical and/or verbal sexual harassment separately (Hesketh et al., 2003; McKenna, Poole, Smith, Coverdale, & Gale, 2003; Zeng et al., 2013) were not included as the overall prevalence of sexual harassment were not reported. In addition, the full texts of two papers were not assessable and were excluded (Kaye, Donald, & Merker, 1994; Madison, 1997).

Study characteristics and quality assessment

Study characteristics are shown in Table 1. Twenty-eight studies (46,470 subjects) reported the 12-month prevalence of sexual harassment, six studies (2,023 subjects) reported the prevalence during nursing career, one study reported the 6-month prevalence (Fute, Mengesha, Wakgari, & Tessema, 2015), one study reported the prevalence in the past 2 years (Cogin & Fish, 2009) and seven studies did not specify the timeframe of the prevalence. The STROBE score ranged from 12-22 with a mean value of 18 among the included studies. All the 43 studies were considered as “high quality”.

Prevalence of sexual harassment

The pooled prevalence of sexual harassment in the past 12 months from 28 studies and within the nursing career from six studies with available data were 12.6% (95% CI: 10.9–14.4%; Figure 2) and 53.4% (95% CI: 23.1–83.7%; Figure 3), respectively. Supplemental Figure 1 and Egger’s tests showed that there was no publication bias for the 12-month prevalence of sexual harassment ($t=0.77$, 95%CI: -4.22-9.28, $P=0.45$). The 6-month prevalence was 13.0% in one study in Ethiopia (Fute et al., 2015), while the prevalence in the past 2 years was 45.0% in one study in Australia (Cogin & Fish, 2009). Seven studies reported the prevalence of sexual harassment without timeframes: the prevalence were 71.5% in Pakistan (Mushtaq et al., 2015), 70.2% in Egypt (Ali et al., 2015), 56.0% in Japan (Hibino, Hitomi, Kambayashi, & Nakamura, 2009), 37.1% in Turkey (Celik & Celik, 2007), 9.4% in Saudi Arabia (Mohamed, 2002), 65.8% in the USA (West, Holoviak, & Figler, 1995) and 71.8% in the USA (Libbus & Bowman, 1994).

Subgroup and meta-regression analyses

The subgroup analyses are presented in Table 2. The 12-month prevalence of sexual harassment assessed by the WHO recommended questionnaires (6.0%) was significantly lower than the figures in studies using self-designed questionnaires (11.5%) or other measures (24.4%). In addition, the 12-month prevalence of sexual harassment was highest in high-income countries (17.2%), followed by lower middle (15.8%), low income (10.0%) and upper middle countries (5.1%). The 12-month prevalence of sexual harassment were higher in studies with smaller sample size (21.0% vs. 7.3%) than those with relatively larger sample size.

Meta-regression analyses revealed that the proportion of female nurses (Coefficient = -0.044, $P < 0.001$, respectively), year of survey (Coefficient = -0.056, $P < 0.001$, respectively), mean age (Coefficient = -0.039, $P < 0.001$, respectively) and sample size (Coefficient = -0.0001, $P < 0.001$, respectively) were significantly associated with the 12-month prevalence (Supplemental Table 1). Sensitivity analyses revealed that after removing each study sequentially, the results of the 12-month prevalence of sexual harassment did not significantly change compared with the primary results.

Discussion

To the best of our knowledge, this was the first comprehensive meta-analysis to examine the prevalence of sexual harassment toward nurses. The pooled prevalence of sexual harassment toward nurses in the past 12 months and during nursing career was 12.6% and 53.4%, respectively.

Findings about the gender difference in prevalence of sexual harassment have been mixed. In some studies workplaces with higher proportion of females were associated with increased risk of sexual harassment (Boafo et al., 2016; Celik & Celik, 2007; Cogin & Fah, 2007), while opposite findings were also reported (Sisawo, Ouedraogo, & Huang, 2017; Zeng et al., 2013). In this meta-analysis, compared with male nurses, female nurses reported lower prevalence of sexual harassment. Female nurses' reactions to sexual harassment could be passive (Adams, Darj,

Wijewardene, & Infanti, 2019). For example, 38.4% and 59.4% of nurse victims of sexual harassment in Egypt and Turkey, respectively chose to ignore the harassment (Ali et al., 2015; Celik & Celik, 2007). Shame and embarrassment are often a deterrent to making a report (Dan, Pinosof, & Riggs, 1995). In addition, sexual harassment by patients was sometimes neglected (Viglianti, Oliverio, & Meeks, 2018). As a result, under-reporting of sexual harassment (Hibino et al., 2009) would most certainly lead to under-estimation of the prevalence in female nurses.

The variation in the prevalence of sexual harassment across countries could be related to the differences in economic and education levels as well as cultural factors (Hibino et al., 2009). For example, nurses in high-income countries usually receive more education and training on occupational safety and health (van Dijk, Bubas, & Smits, 2015) and have more opportunity to report workplace violence including sexual harassment as was found in this meta-analysis. The prevalence of sexual harassment has decreased over time. There is no clear explanation for this finding except for assuming the recently introduced preventive measures on sexual harassment led to the reduction of sexual harassment.

We found that the prevalence of sexual harassment was relatively higher in studies with smaller sample size. No obvious external factor could cause a systemic distortion in smaller studies, therefore we speculate that the results of smaller studies may be more unstable (Cao et al., 2017).

Earlier studies found that nurses who were younger were prone to be sexually harassed (Grieco, 1987; Hibino et al., 2009; Suhaila & Rampal, 2012), which is consistent with our finding that younger age was associated with higher 1-year prevalence of sexual harassment. Age-related difference about the perception of sexual harassment has been previously examined concluding that younger nurses are better aware of sexual harassment and more likely to report it (Hibino et al., 2009).

No universally accepted instrument to assess and recognize sexual harassment currently exist (Nielsen et al., 2017). There was significant difference in the prevalence of sexual harassment between studies using different instruments. The prevalence was lower in studies using the WHO recommended questionnaires than those using self-designed questionnaires or other measures. This article is protected by copyright. All rights reserved

Different content, item numbers and assessment methods (self-reported vs. interviewer-rated) and various cut-off values are likely to lead to different results. It should be noted however, that in the subgroup analysis of the 12-month prevalence, the relatively small number of studies using self-designed questionnaires (N=5) could have created a degree of bias.

Limitations

There are several limitations in this meta-analysis. First, different assessment tools and definitions of sexual harassment were employed across studies, which was associated with high heterogeneity in the results. Second, moderating factors were only limited to basic demographic characteristics. There was inadequate data on important factors related to sexual harassment, such as work shifts, nursing ranking and education level. In addition, perpetrators of harassment and nurses' reactions were not analyzed due to limited data in included studies. Third, the results of subgroup analyses could be potentially moderated by certain confounding variables, which cannot be controlled for in meta-analysis. Lastly, heterogeneity cannot be eliminated in epidemiological surveys even if subgroup analyses are conducted to adjust for the heterogeneity (Li et al., 2016; Long et al., 2014; Winsper et al., 2013).

CONCLUSION

In conclusion, this meta-analysis confirms the high prevalence of sexual harassment toward nurses, particularly in lower middle- and high-income countries. Sexual harassment has deleterious effects (e.g., increased stress and job dissatisfaction and poor work quality and efficiency) on the nursing profession. To ensure workplace safety and equality, preventive strategies should be taught in nursing training, such as the critical consciousness raising amongst nursing students (Harden, 1996), which could also be applied to other health professionals including nurses and approaches of respond to sexual harassment in their workplaces. Apart from staff supports and welfare, better

organizational policies should be developed and implemented at institutional, regional and national levels. There is also a need to introduce effective reporting systems for sexual harassment and to further promote the empowerment of nurses to effectively reduce the risk of sexual harassment.

Conflict of Interest

The authors declare that they have no competing interests related to the topic of this study.
